**See Also**

[prop.test](#) for a general (approximate) test for equal or given proportions.

**Examples**

```
## Conover (1971), p. 97f.
## Under (the assumption of) simple Mendelian inheritance, a cross
## between plants of two particular genotypes produces progeny 1/4 of
## which are "dwarf" and 3/4 of which are "giant", respectively.
## In an experiment to determine if this assumption is reasonable, a
## cross results in progeny having 243 dwarf and 682 giant plants.
## If "giant" is taken as success, the null hypothesis is that p =
## 3/4 and the alternative that p != 3/4.
binom.test(c(682, 243), p = 3/4)
binom.test(682, 682 + 243, p = 3/4) # The same.
## => Data are in agreement with the null hypothesis.
```

Binomial

---

*The Binomial Distribution*

---

**Description**

Density, distribution function, quantile function and random generation for the binomial distribution with parameters size and prob.

This is conventionally interpreted as the number of ‘successes’ in size trials.

**Usage**

```
dbinom(x, size, prob, log = FALSE)
pbinom(q, size, prob, lower.tail = TRUE, log.p = FALSE)
qbinom(p, size, prob, lower.tail = TRUE, log.p = FALSE)
rbinom(n, size, prob)
```

**Arguments**

|                         |                                                                                                           |
|-------------------------|-----------------------------------------------------------------------------------------------------------|
| <code>x, q</code>       | vector of quantiles, the number of successes.                                                             |
| <code>p</code>          | vector of probabilities.                                                                                  |
| <code>n</code>          | number of observations. If <code>length(n) &gt; 1</code> , the length is taken to be the number required. |
| <code>size</code>       | number of trials (zero or more).                                                                          |
| <code>prob</code>       | probability of success on each trial.                                                                     |
| <code>log, log.p</code> | logical; if TRUE, probabilities <code>p</code> are given as <code>log(p)</code> .                         |
| <code>lower.tail</code> | logical; if TRUE (default), probabilities are $P[X \leq x]$ , otherwise, $P[X > x]$ .                     |

**Details**

The binomial distribution with  $\text{size} = n$  and  $\text{prob} = p$  has density

$$p(x) = \binom{n}{x} p^x (1-p)^{n-x}$$

for  $x = 0, \dots, n$ . Note that binomial *coefficients* can be computed by `choose` in R.

If an element of `x` is not integer, the result of `dbinom` is zero, with a warning.

$p(x)$  is computed using Loader's algorithm, see the reference below.

The quantile is defined as the smallest value  $x$  such that  $F(x) \geq p$ , where  $F$  is the distribution function.

**Value**

`dbinom` gives the density, `pbinom` gives the distribution function, `qbinom` gives the quantile function and `rbinom` generates random deviates.

If `size` is not an integer, NaN is returned.

The length of the result is determined by `n` for `rbinom`, and is the maximum of the lengths of the numerical arguments for the other functions.

The numerical arguments other than `n` are recycled to the length of the result. Only the first elements of the logical arguments are used.

**Source**

For `dbinom` a saddle-point expansion is used: see

Catherine Loader (2000). *Fast and Accurate Computation of Binomial Probabilities*; available as <https://www.r-project.org/doc/reports/CLoader-dbinom-2002.pdf>

`pbinom` uses `pbeta`.

`qbinom` uses the Cornish–Fisher Expansion to include a skewness correction to a normal approximation, followed by a search.

`rbinom` (for `size < .Machine$integer.max`) is based on Kachitvichyanukul, V. and Schmeiser, B. W. (1988) Binomial random variate generation. *Communications of the ACM*, **31**, 216–222.  
For larger values it uses inversion.

Examples

```
require(graphics)
# Compute P(45 < X < 55) for X Binomial(100,0.5)
sum(dbinom(46:54, 100, 0.5))

## Using "log = TRUE" for an extended range :
n <- 2000
k <- seq(0, n, by = 20)
plot(k, dbinom(k, n, pi/10, log = TRUE), type = "l", ylab = "log density",
      main = "dbinom(*, log=TRUE) is better than log(dbinom(*))")
lines(k, log(dbinom(k, n, pi/10)), col = "red", lwd = 2)
## extreme points are omitted since dbinom gives 0.
mtext("dbinom(k, log=TRUE)", adj = 0)
mtext("extended range", adj = 0, line = -1, font = 4)
mtext("log(dbinom(k))", col = "red", adj = 1)
```

|--------|------------------------------------|
| biplot | <i>Biplot of Multivariate Data</i> |
|--------|------------------------------------|

---

Description

Plot a biplot on the current graphics device.

Usage

```
biplot(x, ...)
```

## Default S3 method:

```
biplot(x, y, var.axes = TRUE, col, cex = rep(par("cex"), 2),
       xlabs = NULL, ylabs = NULL, expand = 1,
       xlim = NULL, ylim = NULL, arrow.len = 0.1,
       main = NULL, sub = NULL, xlab = NULL, ylab = NULL, ...)
```

Arguments

- `x` The biplot, a fitted object. For `biplot.default`, the first set of points (a two-column matrix), usually associated with observations.
- `y` The second set of points (a two-column matrix), usually associated with variables.
- `var.axes` If `TRUE` the second set of points have arrows representing them as (unscaled) axes.

|                                         |                                                                                                                                                                                                                                                                                                                                                                         |
|-----------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>col</code>                        | A vector of length 2 giving the colours for the first and second set of points respectively (and the corresponding axes). If a single colour is specified it will be used for both sets. If missing the default colour is looked for in the <a href="#">palette</a> : if there it and the next colour as used, otherwise the first two colours of the palette are used. |
| <code>cex</code>                        | The character expansion factor used for labelling the points. The labels can be of different sizes for the two sets by supplying a vector of length two.                                                                                                                                                                                                                |
| <code>xlabs</code>                      | A vector of character strings to label the first set of points: the default is to use the row dimname of <code>x</code> , or <code>1:n</code> if the dimname is <code>NULL</code> .                                                                                                                                                                                     |
| <code>ylabs</code>                      | A vector of character strings to label the second set of points: the default is to use the row dimname of <code>y</code> , or <code>1:n</code> if the dimname is <code>NULL</code> .                                                                                                                                                                                    |
| <code>expand</code>                     | An expansion factor to apply when plotting the second set of points relative to the first. This can be used to tweak the scaling of the two sets to a physically comparable scale.                                                                                                                                                                                      |
| <code>arrow.len</code>                  | The length of the arrow heads on the axes plotted in <code>var.axes</code> is <code>true</code> . The arrow head can be suppressed by <code>arrow.len = 0</code> .                                                                                                                                                                                                      |
| <code>xlim, ylim</code>                 | Limits for the <code>x</code> and <code>y</code> axes in the units of the first set of variables.                                                                                                                                                                                                                                                                       |
| <code>main, sub, xlab, ylab, ...</code> | graphical parameters.                                                                                                                                                                                                                                                                                                                                                   |

### Details

A biplot is plot which aims to represent both the observations and variables of a matrix of multi-variate data on the same plot. There are many variations on biplots (see the references) and perhaps the most widely used one is implemented by [biplot.princomp](#). The function `biplot.default` merely provides the underlying code to plot two sets of variables on the same figure.

Graphical parameters can also be given to `biplot`: the size of `xlabs` and `ylabs` is controlled by `cex`.

### Side Effects

a plot is produced on the current graphics device.

## Description

Produces a biplot (in the strict sense) from the output of [princomp](#) or [prcomp](#)

## Usage

```
## S3 method for class 'prcomp'
biplot(x, choices = 1:2, scale = 1, pc.biplot = FALSE, ...)

## S3 method for class 'princomp'
biplot(x, choices = 1:2, scale = 1, pc.biplot = FALSE, ...)
```

## Arguments

|           |                                                                                                                                                                                                                                                                                                                           |
|-----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| x         | an object of class "princomp".                                                                                                                                                                                                                                                                                            |
| choices   | length 2 vector specifying the components to plot. Only the default is a biplot in the strict sense.                                                                                                                                                                                                                      |
| scale     | The variables are scaled by $\lambda^{\text{scale}}$ and the observations are scaled by $\lambda^{(1-\text{scale})}$ where $\lambda$ are the singular values as computed by <a href="#">princomp</a> . Normally $0 \leq \text{scale} \leq 1$ , and a warning will be issued if the specified scale is outside this range. |
| pc.biplot | If true, use what Gabriel (1971) refers to as a "principal component biplot", with $\lambda = 1$ and observations scaled up by $\sqrt{n}$ and variables scaled down by $\sqrt{n}$ . Then inner products between variables approximate covariances and distances between observations approximate Mahalanobis distance.    |
| ...       | optional arguments to be passed to <a href="#">biplot.default</a> .                                                                                                                                                                                                                                                       |

## Details

This is a method for the generic function `biplot`. There is considerable confusion over the precise definitions: those of the original paper, Gabriel (1971), are followed here. Gabriel and Odoroff (1990) use the same definitions, but their plots actually correspond to `pc.biplot = TRUE`.

## Side Effects

a plot is produced on the current graphics device.

biplot(princomp(USArrests))
```

---

|          |                                    |
|----------|------------------------------------|
| birthday | <i>Probability of coincidences</i> |
|----------|------------------------------------|

---

## Description

Computes answers to a generalised *birthday paradox* problem. `pbirthday` computes the probability of a coincidence and `qbirthday` computes the smallest number of observations needed to have at least a specified probability of coincidence.

## Usage

```
qbirthday(prob = 0.5, classes = 365, coincident = 2)
pbirthday(n, classes = 365, coincident = 2)
```

## Arguments

|            |                                                         |
|------------|---------------------------------------------------------|
| classes    | How many distinct categories the people could fall into |
| prob       | The desired probability of coincidence                  |
| n          | The number of people                                    |
| coincident | The number of people to fall in the same category       |

## Details

The birthday paradox is that a very small number of people, 23, suffices to have a 50–50 chance that two or more of them have the same birthday. This function generalises the calculation to probabilities other than 0.5, numbers of coincident events other than 2, and numbers of classes other than 365.

The formula used is approximate for `coincident > 2`. The approximation is very good for moderate values of `prob` but less good for very small probabilities.

## Value

|                        |                                                                                                                                                                                        |
|------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>qbirthday</code> | Minimum number of people needed for a probability of at least <code>prob</code> that <code>k</code> or more of them have the same one out of <code>classes</code> equiprobable labels. |
| <code>pbirthday</code> | Probability of the specified coincidence.                                                                                                                                              |

## Examples

```
require(graphics)

## the standard version
qbirthday() # 23
## probability of > 2 people with the same birthday
pbirthday(23, coincident = 3)

## examples from Diaconis & Mosteller p. 858.
## 'coincidence' is that husband, wife, daughter all born on the 16th
qbirthday(classes = 30, coincident = 3) # approximately 18
qbirthday(coincident = 4) # exact value 187
qbirthday(coincident = 10) # exact value 1181

## same 4-digit PIN number
qbirthday(classes = 10^4)

## 0.9 probability of three or more coincident birthdays
qbirthday(coincident = 3, prob = 0.9)

## Chance of 4 or more coincident birthdays in 150 people
pbirthday(150, coincident = 4)

## 100 or more coincident birthdays in 1000 people: very rare
pbirthday(1000, coincident = 100)
```

---

Box.test

*Box-Pierce and Ljung-Box Tests*

---

## Description

Compute the Box–Pierce or Ljung–Box test statistic for examining the null hypothesis of independence in a given time series. These are sometimes known as ‘portmanteau’ tests.

## Usage

```
Box.test(x, lag = 1, type = c("Box-Pierce", "Ljung-Box"), fitdf = 0)
```

## Arguments

|                    |                                                                                           |
|--------------------|-------------------------------------------------------------------------------------------|
| <code>x</code>     | a numeric vector or univariate time series.                                               |
| <code>lag</code>   | the statistic will be based on lag autocorrelation coefficients.                          |
| <code>type</code>  | test to be performed: partial matching is used.                                           |
| <code>fitdf</code> | number of degrees of freedom to be subtracted if <code>x</code> is a series of residuals. |

## Details

These tests are sometimes applied to the residuals from an ARMA( $p$ ,  $q$ ) fit, in which case the references suggest a better approximation to the null-hypothesis distribution is obtained by setting `fitdf = p+q`, provided of course that `lag > fitdf`.

**Value**

A list with class "htest" containing the following components:

|           |                                                                                                                                    |
|-----------|------------------------------------------------------------------------------------------------------------------------------------|
| statistic | the value of the test statistic.                                                                                                   |
| parameter | the degrees of freedom of the approximate chi-squared distribution of the test statistic (taking <code>fitdf</code> into account). |
| p.value   | the p-value of the test.                                                                                                           |
| method    | a character string indicating which type of test was performed.                                                                    |
| data.name | a character string giving the name of the data.                                                                                    |

**Note**

Missing values are not handled.

C

*Sets Contrasts for a Factor*

---

**Description**

Sets the "contrasts" attribute for the factor.

**Usage**

```
C(object, contr, how.many, ...)
```

**Arguments**

|          |                                                                                                                                                                                             |
|----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| object   | a factor or ordered factor                                                                                                                                                                  |
| contr    | which contrasts to use. Can be a matrix with one row for each level of the factor or a suitable function like <code>contr.poly</code> or a character string giving the name of the function |
| how.many | the number of contrasts to set, by default one less than <code>nlevels(object)</code> .                                                                                                     |
| ...      | additional arguments for the function <code>contr</code> .                                                                                                                                  |

**Details**

For compatibility with S, `contr` can be `treatment`, `helmert`, `sum` or `poly` (without quotes) as shorthand for `contr.treatment` and so on.

**Value**

The factor object with the "contrasts" attribute set.

**See Also**

[contrasts](#), [contr.sum](#), etc.

**Examples**

```
## reset contrasts to defaults
options(contrasts = c("contr.treatment", "contr.poly"))
tens <- with(warpbreaks, C(tension, poly, 1))
attributes(tens)
## tension SHOULD be an ordered factor, but as it is not we can use
aov(breaks ~ wool + tens + tension, data = warpbreaks)

## show the use of ... The default contrast is contr.treatment here
summary(lm(breaks ~ wool + C(tension, base = 2), data = warpbreaks))

# following on from help(esoph)
model3 <- glm(cbind(ncases, ncontrols) ~ agegp + C(tobgp, , 1) +
  C(alcgp, , 1), data = esoph, family = binomial())
summary(model3)
```

---

cancor

---

*Canonical Correlations*

---

**Description**

Compute the canonical correlations between two data matrices.

**Usage**

```
cancor(x, y, xcenter = TRUE, ycenter = TRUE)
```

**Arguments**

|                |                                                                  |
|----------------|------------------------------------------------------------------|
| <code>x</code> | numeric matrix ( $n \times p_1$ ), containing the x coordinates. |
| <code>y</code> | numeric matrix ( $n \times p_2$ ), containing the y coordinates. |

|         |                                                                                                                                                                                                                                                                          |
|---------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| xcenter | logical or numeric vector of length $p_1$ , describing any centering to be done on the x values before the analysis. If TRUE (default), subtract the column means. If FALSE, do not adjust the columns. Otherwise, a vector of values to be subtracted from the columns. |
| ycenter | analogous to xcenter, but for the y values.                                                                                                                                                                                                                              |

### Details

The canonical correlation analysis seeks linear combinations of the y variables which are well explained by linear combinations of the x variables. The relationship is symmetric as ‘well explained’ is measured by correlations.

### Value

A list containing the following components:

|         |                                             |
|---------|---------------------------------------------|
| cor     | correlations.                               |
| xcoef   | estimated coefficients for the x variables. |
| ycoef   | estimated coefficients for the y variables. |
| xcenter | the values used to adjust the x variables.  |
| ycenter | the values used to adjust the x variables.  |

### Examples

```
## signs of results are random
pop <- LifeCycleSavings[, 2:3]
oec <- LifeCycleSavings[, -(2:3)]
cancor(pop, oec)

x <- matrix(rnorm(150), 50, 3)
y <- matrix(rnorm(250), 50, 5)
(cxy <- cancor(x, y))
all(abs(cor(x %%% cxy$xcoef,
            y %%% cxy$ycoef)[,1:3] - diag(cxy $ cor)) < 1e-15)
all(abs(cor(x %%% cxy$xcoef) - diag(3)) < 1e-15)
all(abs(cor(y %%% cxy$ycoef) - diag(5)) < 1e-15)
```

## Description

Simple utilities returning (non-missing) case names, and (non-eliminated) variable names.

## Usage

```
case.names(object, ...)
## S3 method for class 'lm'
case.names(object, full = FALSE, ...)

variable.names(object, ...)
## S3 method for class 'lm'
variable.names(object, full = FALSE, ...)
```

## Arguments

|        |                                                                         |
|--------|-------------------------------------------------------------------------|
| object | an R object, typically a fitted model.                                  |
| full   | logical; if TRUE, all names (including zero weights, ...) are returned. |
| ...    | further arguments passed to or from other methods.                      |

## Value

A character vector.

## See Also

[lm](#); further, [all.names](#), [all.vars](#) for functions with a similar name but only slightly related purpose.

## Examples

```
x <- 1:20
y <- setNames(x + (x/4 - 2)^3 + rnorm(20, sd = 3),
             paste("0", x, sep = "."))
ww <- rep(1, 20); ww[13] <- 0
summary(lmxy <- lm(y ~ x + I(x^2)+I(x^3) + I((x-10)^2), weights = ww),
       correlation = TRUE)
variable.names(lmxy)
variable.names(lmxy, full = TRUE) # includes the last
case.names(lmxy)
case.names(lmxy, full = TRUE)     # includes the 0-weight case
```

**Description**

Density, distribution function, quantile function and random generation for the Cauchy distribution with location parameter `location` and scale parameter `scale`.

**Usage**

```
dcauchy(x, location = 0, scale = 1, log = FALSE)
pcauchy(q, location = 0, scale = 1, lower.tail = TRUE, log.p = FALSE)
qcauchy(p, location = 0, scale = 1, lower.tail = TRUE, log.p = FALSE)
rcauchy(n, location = 0, scale = 1)
```

**Arguments**

|                              |                                                                                                           |
|------------------------------|-----------------------------------------------------------------------------------------------------------|
| <code>x, q</code>            | vector of quantiles.                                                                                      |
| <code>p</code>               | vector of probabilities.                                                                                  |
| <code>n</code>               | number of observations. If <code>length(n) &gt; 1</code> , the length is taken to be the number required. |
| <code>location, scale</code> | location and scale parameters.                                                                            |
| <code>log, log.p</code>      | logical; if TRUE, probabilities <code>p</code> are given as $\log(p)$ .                                   |
| <code>lower.tail</code>      | logical; if TRUE (default), probabilities are $P[X \leq x]$ , otherwise, $P[X > x]$ .                     |

**Details**

If `location` or `scale` are not specified, they assume the default values of 0 and 1 respectively.

The Cauchy distribution with location  $l$  and scale  $s$  has density

$$f(x) = \frac{1}{\pi s} \left( 1 + \left( \frac{x - l}{s} \right)^2 \right)^{-1}$$

for all  $x$ .

**Value**

`dcauchy`, `pcauchy`, and `qcauchy` are respectively the density, distribution function and quantile function of the Cauchy distribution. `rcauchy` generates random deviates from the Cauchy.

The length of the result is determined by `n` for `rcauchy`, and is the maximum of the lengths of the numerical arguments for the other functions.

The numerical arguments other than `n` are recycled to the length of the result. Only the first elements of the logical arguments are used.

**Source**

`dcauchy`, `pcauchy` and `qcauchy` are all calculated from numerically stable versions of the definitions.

`rcauchy` uses inversion.

|            |                                                  |
|------------|--------------------------------------------------|
| chisq.test | <i>Pearson's Chi-squared Test for Count Data</i> |
|------------|--------------------------------------------------|

---

## Description

`chisq.test` performs chi-squared contingency table tests and goodness-of-fit tests.

## Usage

```
chisq.test(x, y = NULL, correct = TRUE,
           p = rep(1/length(x), length(x)), rescale.p = FALSE,
           simulate.p.value = FALSE, B = 2000)
```

## Arguments

|                  |                                                                                                                                                                                                                                                                                                                     |
|------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| x                | a numeric vector or matrix. x and y can also both be factors.                                                                                                                                                                                                                                                       |
| y                | a numeric vector; ignored if x is a matrix. If x is a factor, y should be a factor of the same length.                                                                                                                                                                                                              |
| correct          | a logical indicating whether to apply continuity correction when computing the test statistic for 2 by 2 tables: one half is subtracted from all $ O - E $ differences; however, the correction will not be bigger than the differences themselves. No correction is done if <code>simulate.p.value = TRUE</code> . |
| p                | a vector of probabilities of the same length as x. An error is given if any entry of p is negative.                                                                                                                                                                                                                 |
| rescale.p        | a logical scalar; if TRUE then p is rescaled (if necessary) to sum to 1. If <code>rescale.p</code> is FALSE, and p does not sum to 1, an error is given.                                                                                                                                                            |
| simulate.p.value | a logical indicating whether to compute p-values by Monte Carlo simulation.                                                                                                                                                                                                                                         |
| B                | an integer specifying the number of replicates used in the Monte Carlo test.                                                                                                                                                                                                                                        |

## Details

If  $x$  is a matrix with one row or column, or if  $x$  is a vector and  $y$  is not given, then a *goodness-of-fit test* is performed ( $x$  is treated as a one-dimensional contingency table). The entries of  $x$  must be non-negative integers. In this case, the hypothesis tested is whether the population probabilities equal those in  $p$ , or are all equal if  $p$  is not given.

If  $x$  is a matrix with at least two rows and columns, it is taken as a two-dimensional contingency table: the entries of  $x$  must be non-negative integers. Otherwise,  $x$  and  $y$  must be vectors or factors of the same length; cases with missing values are removed, the objects are coerced to factors, and the contingency table is computed from these. Then Pearson's chi-squared test is performed of the null hypothesis that the joint distribution of the cell counts in a 2-dimensional contingency table is the product of the row and column marginals.

If `simulate.p.value` is FALSE, the p-value is computed from the asymptotic chi-squared distribution of the test statistic; continuity correction is only used in the 2-by-2 case (if `correct` is TRUE, the default). Otherwise the p-value is computed for a Monte Carlo test (Hope, 1968) with  $B$  replicates. The default  $B = 2000$  implies a minimum p-value of about 0.0005 ( $1/(B + 1)$ ).

In the contingency table case, simulation is done by random sampling from the set of all contingency tables with given marginals, and works only if the marginals are strictly positive. Continuity correction is never used, and the statistic is quoted without it. Note that this is not the usual sampling situation assumed for the chi-squared test but rather that for Fisher's exact test.

In the goodness-of-fit case simulation is done by random sampling from the discrete distribution specified by  $p$ , each sample being of size  $n = \text{sum}(x)$ . This simulation is done in R and may be slow.

## Value

A list with class "htest" containing the following components:

|                        |                                                                                                                                                                                                                    |
|------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>statistic</code> | the value the chi-squared test statistic.                                                                                                                                                                          |
| <code>parameter</code> | the degrees of freedom of the approximate chi-squared distribution of the test statistic, NA if the p-value is computed by Monte Carlo simulation.                                                                 |
| <code>p.value</code>   | the p-value for the test.                                                                                                                                                                                          |
| <code>method</code>    | a character string indicating the type of test performed, and whether Monte Carlo simulation or continuity correction was used.                                                                                    |
| <code>data.name</code> | a character string giving the name(s) of the data.                                                                                                                                                                 |
| <code>observed</code>  | the observed counts.                                                                                                                                                                                               |
| <code>expected</code>  | the expected counts under the null hypothesis.                                                                                                                                                                     |
| <code>residuals</code> | the Pearson residuals, $(\text{observed} - \text{expected}) / \sqrt{\text{expected}}$ .                                                                                                                            |
| <code>stdres</code>    | standardized residuals, $(\text{observed} - \text{expected}) / \sqrt{V}$ , where $V$ is the residual cell variance (Agresti, 2007, section 2.4.5 for the case where $x$ is a matrix, $n * p * (1 - p)$ otherwise). |

## Source

The code for Monte Carlo simulation is a C translation of the Fortran algorithm of Patefield (1981).

Chisquare

*The (non-central) Chi-Squared Distribution***Description**

Density, distribution function, quantile function and random generation for the chi-squared ( $\chi^2$ ) distribution with `df` degrees of freedom and optional non-centrality parameter `ncp`.

**Usage**

```
dchisq(x, df, ncp = 0, log = FALSE)
pchisq(q, df, ncp = 0, lower.tail = TRUE, log.p = FALSE)
qchisq(p, df, ncp = 0, lower.tail = TRUE, log.p = FALSE)
rchisq(n, df, ncp = 0)
```

**Arguments**

|                         |                                                                                                           |
|-------------------------|-----------------------------------------------------------------------------------------------------------|
| <code>x, q</code>       | vector of quantiles.                                                                                      |
| <code>p</code>          | vector of probabilities.                                                                                  |
| <code>n</code>          | number of observations. If <code>length(n) &gt; 1</code> , the length is taken to be the number required. |
| <code>df</code>         | degrees of freedom (non-negative, but can be non-integer).                                                |
| <code>ncp</code>        | non-centrality parameter (non-negative).                                                                  |
| <code>log, log.p</code> | logical; if TRUE, probabilities <code>p</code> are given as <code>log(p)</code> .                         |
| <code>lower.tail</code> | logical; if TRUE (default), probabilities are $P[X \leq x]$ , otherwise, $P[X > x]$ .                     |

**Details**

The chi-squared distribution with  $df = n \geq 0$  degrees of freedom has density

$$f_n(x) = \frac{1}{2^{n/2} \Gamma(n/2)} x^{n/2-1} e^{-x/2}$$

for  $x > 0$ , where  $f_0(x) := \lim_{n \rightarrow 0} f_n(x) = \delta_0(x)$ , a point mass at zero, is not a density function proper, but a “ $\delta$  distribution”.

The mean and variance are  $n$  and  $2n$ .

The non-central chi-squared distribution with  $df = n$  degrees of freedom and non-centrality parameter  $ncp = \lambda$  has density

$$f(x) = f_{n,\lambda}(x) = e^{-\lambda/2} \sum_{r=0}^{\infty} \frac{(\lambda/2)^r}{r!} f_{n+2r}(x)$$

for  $x \geq 0$ . For integer  $n$ , this is the distribution of the sum of squares of  $n$  normals each with variance one,  $\lambda$  being the sum of squares of the normal means; further,

$$E(X) = n + \lambda, \text{Var}(X) = 2(n + 2 * \lambda), \text{ and } E((X - E(X))^3) = 8(n + 3 * \lambda).$$

Note that the degrees of freedom  $df = n$ , can be non-integer, and also  $n = 0$  which is relevant for non-centrality  $\lambda > 0$ , see Johnson et al. (1995, chapter 29). In that (noncentral, zero  $df$ ) case, the distribution is a mixture of a point mass at  $x = 0$  (of size `pchisq(0, df=0, ncp=ncp)`) and a continuous part, and `dchisq()` is *not* a density with respect to that mixture measure but rather the limit of the density for  $df \rightarrow 0$ .

Note that `ncp` values larger than about `1e5` (and even smaller) may give inaccurate results with many warnings for `pchisq` and `qchisq`.

**Value**

`dchisq` gives the density, `pchisq` gives the distribution function, `qchisq` gives the quantile function, and `rchisq` generates random deviates.

Invalid arguments will result in return value NaN, with a warning.

The length of the result is determined by `n` for `rchisq`, and is the maximum of the lengths of the numerical arguments for the other functions.

The numerical arguments other than `n` are recycled to the length of the result. Only the first elements of the logical arguments are used.

**Note**

Supplying `ncp = 0` uses the algorithm for the non-central distribution, which is not the same algorithm used if `ncp` is omitted. This is to give consistent behaviour in extreme cases with values of `ncp` very near zero.

The code for non-zero `ncp` is principally intended to be used for moderate values of `ncp`: it will not be highly accurate, especially in the tails, for large values.

**Source**

The central cases are computed via the gamma distribution.

The non-central `dchisq` and `rchisq` are computed as a Poisson mixture of central chi-squares (Johnson et al., 1995, p.436).

The non-central `pchisq` is for `ncp < 80` computed from the Poisson mixture of central chi-squares and for larger `ncp` via a C translation of

Ding, C. G. (1992) Algorithm AS275: Computing the non-central chi-squared distribution function. *Applied Statistics*, **41** 478–482.

which computes the lower tail only (so the upper tail suffers from cancellation and a warning will be given when this is likely to be significant).

The non-central `qchisq` is based on inversion of `pchisq`.

cmdscale

*Classical (Metric) Multidimensional Scaling*

## Description

Classical multidimensional scaling (MDS) of a data matrix. Also known as *principal coordinates analysis* (Gower, 1966).

## Usage

```
cmdscale(d, k = 2, eig = FALSE, add = FALSE, x.ret = FALSE,
        list. = eig || add || x.ret)
```

### Arguments

|                    |                                                                                                                                                                          |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>d</code>     | a distance structure such as that returned by <code>dist</code> or a full symmetric matrix containing the dissimilarities.                                               |
| <code>k</code>     | the maximum dimension of the space which the data are to be represented in; must be in $\{1, 2, \dots, n - 1\}$ .                                                        |
| <code>eig</code>   | indicates whether eigenvalues should be returned.                                                                                                                        |
| <code>add</code>   | logical indicating if an additive constant $c^*$ should be computed, and added to the non-diagonal dissimilarities such that the modified dissimilarities are Euclidean. |
| <code>x.ret</code> | indicates whether the doubly centred symmetric distance matrix should be returned.                                                                                       |
| <code>list.</code> | logical indicating if a <code>list</code> should be returned or just the $n \times k$ matrix, see ‘Value:’.                                                              |

### Details

Multidimensional scaling takes a set of dissimilarities and returns a set of points such that the distances between the points are approximately equal to the dissimilarities. (It is a major part of what ecologists call ‘ordination’.)

A set of Euclidean distances on  $n$  points can be represented exactly in at most  $n - 1$  dimensions. `cmdscale` follows the analysis of Mardia (1978), and returns the best-fitting  $k$ -dimensional representation, where  $k$  may be less than the argument `k`.

The representation is only determined up to location (`cmdscale` takes the column means of the configuration to be at the origin), rotations and reflections. The configuration returned is given in principal-component axes, so the reflection chosen may differ between **R** platforms (see [prcomp](#)).

When `add = TRUE`, a minimal additive constant  $c^*$  is computed such that the dissimilarities  $d_{ij} + c^*$  are Euclidean and hence can be represented in  $n - 1$  dimensions. Whereas **S** (Becker et al., 1988) computes this constant using an approximation suggested by Torgerson, **R** uses the analytical solution of Cailliez (1983), see also Cox and Cox (2001). Note that because of numerical errors the computed eigenvalues need not all be non-negative, and even theoretically the representation could be in fewer than  $n - 1$  dimensions.

### Value

If `list.` is false (as per default), a matrix with `k` columns whose rows give the coordinates of the points chosen to represent the dissimilarities.

Otherwise, a `list` containing the following components.

|                     |                                                                                                                                                                                                                                                     |
|---------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>points</code> | a matrix with up to <code>k</code> columns whose rows give the coordinates of the points chosen to represent the dissimilarities.                                                                                                                   |
| <code>eig</code>    | the $n$ eigenvalues computed during the scaling process if <code>eig</code> is true. <b>NB:</b> versions of <b>R</b> before 2.12.1 returned only <code>k</code> but were documented to return $n - 1$ .                                             |
| <code>x</code>      | the doubly centered distance matrix if <code>x.ret</code> is true.                                                                                                                                                                                  |
| <code>ac</code>     | the additive constant $c^*$ , $\emptyset$ if <code>add = FALSE</code> .                                                                                                                                                                             |
| <code>GOF</code>    | a numeric vector of length 2, equal to say $(g_1, g_2)$ , where $g_i = (\sum_{j=1}^k \lambda_j) / (\sum_{j=1}^n T_i(\lambda_j))$ , where $\lambda_j$ are the eigenvalues (sorted in decreasing order), $T_1(v) =  v $ , and $T_2(v) = \max(v, 0)$ . |

[isoMDS](#) and [sammon](#) in package **MASS** provide alternative methods of multidimensional scaling.

## Examples

```
require(graphics)

loc <- cmdscale(eurodist)
x <- loc[, 1]
y <- -loc[, 2] # reflect so North is at the top
## note asp = 1, to ensure Euclidean distances are represented correctly
plot(x, y, type = "n", xlab = "", ylab = "", asp = 1, axes = FALSE,
     main = "cmdscale(eurodist)")
text(x, y, rownames(loc), cex = 0.6)
```

---

coef

*Extract Model Coefficients*

---

## Description

coef is a generic function which extracts model coefficients from objects returned by modeling functions. coefficients is an *alias* for it.

## Usage

```
coef(object, ...)
coefficients(object, ...)
## Default S3 method:
coef(object, complete = TRUE, ...)
## S3 method for class 'aov'
coef(object, complete = FALSE, ...)
```

**Arguments**

|          |                                                                                                                                                                                                                                                                                                                                                                                 |
|----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| object   | an object for which the extraction of model coefficients is meaningful.                                                                                                                                                                                                                                                                                                         |
| complete | for the default (used for <code>lm</code> , etc) and <code>aov</code> methods: logical indicating if the full coefficient vector should be returned also in case of an over-determined system where some coefficients will be set to <code>NA</code> , see also <code>alias</code> . Note that the default <i>differs</i> for <code>lm()</code> and <code>aov()</code> results. |
| ...      | other arguments.                                                                                                                                                                                                                                                                                                                                                                |

**Details**

All object classes which are returned by model fitting functions should provide a `coef` method or use the default one. (Note that the method is for `coef` and not coefficients.)

The "aov" method does not report aliased coefficients (see `alias`) by default where `complete = FALSE`.

The `complete` argument also exists for compatibility with `vcov` methods, and `coef` and `aov` methods for other classes should typically also keep the `complete = *` behavior in sync. By that, with `p <- length(coef(obj, complete = TF))`, `dim(vcov(obj, complete = TF)) == c(p,p)` will be fulfilled for both `complete` settings and the default.

**Value**

Coefficients extracted from the model object `object`.

For standard model fitting classes this will be a named numeric vector. For "maov" objects (produced by `aov`) it will be a matrix.

**References**

Chambers, J. M. and Hastie, T. J. (1992) *Statistical Models in S*. Wadsworth & Brooks/Cole.

**See Also**

`fitted.values` and `residuals` for related methods; `glm`, `lm` for model fitting.

**Examples**

```
x <- 1:5; coef(lm(c(1:3, 7, 6) ~ x))
```

---

complete.cases

*Find Complete Cases*

---

**Description**

Return a logical vector indicating which cases are complete, i.e., have no missing values.

**Usage**

```
complete.cases(...)
```

**Arguments**

... a sequence of vectors, matrices and data frames.

**Value**

A logical vector specifying which observations/rows have no missing values across the entire sequence.

**Note**

A current limitation of this function is that it uses low level functions to determine lengths and missingness, ignoring the class. This will lead to spurious errors when some columns have classes with `length` or `is.na` methods, for example `"POSIXlt"`, as described in [PR#16648](#).

**See Also**

[is.na](#), [na.omit](#), [na.fail](#).

**Examples**

```
x <- airquality[, -1] # x is a regression design matrix
y <- airquality[, 1] # y is the corresponding response

stopifnot(complete.cases(y) != is.na(y))
ok <- complete.cases(x, y)
sum(!ok) # how many are not "ok" ?
x <- x[ok,]
y <- y[ok]
```

---

confint

---

*Confidence Intervals for Model Parameters*

---

**Description**

Computes confidence intervals for one or more parameters in a fitted model. There is a default and a method for objects inheriting from class `"lm"`.

**Usage**

```
confint(object, parm, level = 0.95, ...)
## Default S3 method:
confint(object, parm, level = 0.95, ...)
## S3 method for class 'lm'
confint(object, parm, level = 0.95, ...)
## S3 method for class 'glm'
confint(object, parm, level = 0.95, trace = FALSE, test=c("LRT", "Rao"), ...)
## S3 method for class 'nls'
confint(object, parm, level = 0.95, ...)
```

**Arguments**

|        |                                                                                                                                                                       |
|--------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| object | a fitted model object.                                                                                                                                                |
| parm   | a specification of which parameters are to be given confidence intervals, either a vector of numbers or a vector of names. If missing, all parameters are considered. |

|       |                                                      |
|-------|------------------------------------------------------|
| level | the confidence level required.                       |
| trace | logical. Should profiling be traced?                 |
| test  | use Likelihood Ratio or Rao Score test in profiling. |
| ...   | additional argument(s) for methods.                  |

### Details

confint is a generic function. The default method assumes normality, and needs suitable `coef` and `vcov` methods to be available. The default method can be called directly for comparison with other methods.

For objects of class "lm" the direct formulae based on  $t$  values are used.

Methods for classes "glm" and "nls" call the appropriate profile method, then find the confidence intervals by interpolation in the profile traces. If the profile object is already available it can be used as the main argument rather than the fitted model object itself.

### Value

A matrix (or vector) with columns giving lower and upper confidence limits for each parameter. These will be labelled as (1-level)/2 and 1 - (1-level)/2 in % (by default 2.5% and 97.5%).

### References

### See Also

Original versions: `confint.glm` and `confint.nls` in package **MASS**.

### Examples

```
fit <- lm(100/mpg ~ disp + hp + wt + am, data = mtcars)
confint(fit)
confint(fit, "wt")

## from example(glm)
counts <- c(18,17,15,20,10,20,25,13,12)
outcome <- gl(3, 1, 9); treatment <- gl(3, 3)
glm.D93 <- glm(counts ~ outcome + treatment, family = poisson())
confint(glm.D93)
confint.default(glm.D93) # based on asymptotic normality
```

### Description

Minimise a function subject to linear inequality constraints using an adaptive barrier algorithm.

**Usage**

```
constrOptim(theta, f, grad, ui, ci, mu = 1e-04, control = list(),
            method = if(is.null(grad)) "Nelder-Mead" else "BFGS",
            outer.iterations = 100, outer.eps = 1e-05, ...,
            hessian = FALSE)
```

**Arguments**

|                                       |                                                                                                                                                                       |
|---------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>theta</code>                    | numeric (vector) starting value (of length $p$ ): must be in the feasible region.                                                                                     |
| <code>f</code>                        | function to minimise (see below).                                                                                                                                     |
| <code>grad</code>                     | gradient of <code>f</code> (a <a href="#">function</a> as well), or <code>NULL</code> (see below).                                                                    |
| <code>ui</code>                       | constraint matrix ( $k \times p$ ), see below.                                                                                                                        |
| <code>ci</code>                       | constraint vector of length $k$ (see below).                                                                                                                          |
| <code>mu</code>                       | (Small) tuning parameter.                                                                                                                                             |
| <code>control, method, hessian</code> | passed to <a href="#">optim</a> .                                                                                                                                     |
| <code>outer.iterations</code>         | iterations of the barrier algorithm.                                                                                                                                  |
| <code>outer.eps</code>                | non-negative number; the relative convergence tolerance of the barrier algorithm.                                                                                     |
| <code>...</code>                      | Other named arguments to be passed to <code>f</code> and <code>grad</code> : needs to be passed through <a href="#">optim</a> so should not match its argument names. |

**Details**

The feasible region is defined by `ui %*% theta - ci >= 0`. The starting value must be in the interior of the feasible region, but the minimum may be on the boundary.

A logarithmic barrier is added to enforce the constraints and then [optim](#) is called. The barrier function is chosen so that the objective function should decrease at each outer iteration. Minima in the interior of the feasible region are typically found quite quickly, but a substantial number of outer iterations may be needed for a minimum on the boundary.

The tuning parameter `mu` multiplies the barrier term. Its precise value is often relatively unimportant. As `mu` increases the augmented objective function becomes closer to the original objective function but also less smooth near the boundary of the feasible region.

Any `optim` method that permits infinite values for the objective function may be used (currently all but "L-BFGS-B").

The objective function `f` takes as first argument the vector of parameters over which minimisation is to take place. It should return a scalar result. Optional arguments `...` will be passed to `optim` and then (if not used by `optim`) to `f`. As with `optim`, the default is to minimise, but maximisation can be performed by setting `control$fnscale` to a negative value.

The gradient function `grad` must be supplied except with `method = "Nelder-Mead"`. It should take arguments matching those of `f` and return a vector containing the gradient.

**Value**

As for [optim](#), but with two extra components: `barrier.value` giving the value of the barrier function at the optimum and `outer.iterations` gives the number of outer iterations (calls to `optim`). The counts component contains the *sum* of all `optim()`\$counts.

contrast

(Possibly Sparse) Contrast Matrices

---

## Description

Return a matrix of contrasts.

## Usage

```
contr.helmert(n, contrasts = TRUE, sparse = FALSE)
contr.poly(n, scores = 1:n, contrasts = TRUE, sparse = FALSE)
contr.sum(n, contrasts = TRUE, sparse = FALSE)
contr.treatment(n, base = 1, contrasts = TRUE, sparse = FALSE)
contr.SAS(n, contrasts = TRUE, sparse = FALSE)
```

## Arguments

|           |                                                                                                                     |
|-----------|---------------------------------------------------------------------------------------------------------------------|
| n         | a vector of levels for a factor, or the number of levels.                                                           |
| contrasts | a logical indicating whether contrasts should be computed.                                                          |
| sparse    | logical indicating if the result should be sparse (of class <code>dgCMatrix</code> ), using package <b>Matrix</b> . |
| scores    | the set of values over which orthogonal polynomials are to be computed.                                             |
| base      | an integer specifying which group is considered the baseline group. Ignored if contrasts is FALSE.                  |

## Details

These functions are used for creating contrast matrices for use in fitting analysis of variance and regression models. The columns of the resulting matrices contain contrasts which can be used for coding a factor with n levels. The returned value contains the computed contrasts. If the argument contrasts is FALSE a square indicator matrix (the dummy coding) is returned **except** for `contr.poly` (which includes the 0-degree, i.e. constant, polynomial when contrasts = FALSE).

`contr.helmert` returns Helmert contrasts, which contrast the second level with the first, the third with the average of the first two, and so on. `contr.poly` returns contrasts based on orthogonal polynomials. `contr.sum` uses ‘sum to zero contrasts’.

`contr.treatment` contrasts each level with the baseline level (specified by base): the baseline level is omitted. Note that this does not produce ‘contrasts’ as defined in the standard theory for linear models as they are not orthogonal to the intercept.

`contr.SAS` is a wrapper for `contr.treatment` that sets the base level to be the last level of the factor. The coefficients produced when using these contrasts should be equivalent to those produced by many (but not all) SAS procedures.

For consistency, sparse is an argument to all these contrast functions, however sparse = TRUE for `contr.poly` is typically pointless and is rarely useful for `contr.helmert`.

## Value

A matrix with n rows and k columns, with k=n-1 if contrasts is TRUE and k=n if contrasts is FALSE.

contrasts

*Get and Set Contrast Matrices*

---

## Description

Set and view the contrasts associated with a factor.

## Usage

```
contrasts(x, contrasts = TRUE, sparse = FALSE)
contrasts(x, how.many = NULL) <- value
```

## Arguments

|           |                                                                                                                                                                                                                                                        |
|-----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| x         | a factor or a logical variable.                                                                                                                                                                                                                        |
| contrasts | logical. See ‘Details’.                                                                                                                                                                                                                                |
| sparse    | logical indicating if the result should be sparse (of class <code>dgCMatrix</code> ), using package <b>Matrix</b> .                                                                                                                                    |
| how.many  | integer number indicating how many contrasts should be made. Defaults to one less than the number of levels of x. This need not be the same as the number of columns of value.                                                                         |
| value     | either a numeric matrix (or a sparse or dense matrix of a class extending <code>dMatrix</code> (pkg <b>Matrix</b> ) whose columns give coefficients for contrasts in the levels of x, or (the quoted name of) a function which computes such matrices. |

## Details

If contrasts are not set for a factor the default functions from `options("contrasts")` are used.

A logical vector x is converted into a two-level factor with levels `c(FALSE, TRUE)` (regardless of which levels occur in the variable).

The argument `contrasts` is ignored if x has a matrix `contrasts` attribute set. Otherwise if `contrasts = TRUE` it is passed to a contrasts function such as `contr.treatment` and if `contrasts = FALSE` an identity matrix is returned. Suitable functions have a first argument which is the character vector of levels, a named argument `contrasts` (always called with `contrasts = TRUE`) and optionally a logical argument `sparse`.

If value supplies more than how.many contrasts, the first how.many are used. If too few are supplied, a suitable contrast matrix is created by extending value after ensuring its columns are contrasts (orthogonal to the constant term) and not collinear.

convolve

---

*Convolution of Sequences via FFT*

---

## Description

Use the Fast Fourier Transform to compute the several kinds of convolutions of two sequences.

## Usage

```
convolve(x, y, conj = TRUE, type = c("circular", "open", "filter"))
```

## Arguments

|      |                                                                                                                                                                                                                                                                                                                                                              |
|------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| x, y | numeric sequences <i>of the same length</i> to be convolved.                                                                                                                                                                                                                                                                                                 |
| conj | logical; if TRUE, take the complex <i>conjugate</i> before back-transforming (default, and used for usual convolution).                                                                                                                                                                                                                                      |
| type | character; partially matched to "circular", "open", "filter". For "circular", the two sequences are treated as <i>circular</i> , i.e., periodic. For "open" and "filter", the sequences are padded with 0s (from left and right) first; "filter" returns the middle sub-vector of "open", namely, the result of running a weighted mean of x with weights y. |

## Details

The Fast Fourier Transform, `fft`, is used for efficiency.

The input sequences `x` and `y` must have the same length if `circular` is `true`.

Note that the usual definition of convolution of two sequences `x` and `y` is given by `convolve(x, rev(y), type = "o")`.

## Value

If `r <- convolve(x, y, type = "open")` and `n <- length(x)`, `m <- length(y)`, then

$$r_k = \sum_i x_{k-m+i} y_i$$

where the sum is over all valid indices  $i$ , for  $k = 1, \dots, n + m - 1$ .

If `type == "circular"`,  $n = m$  is required, and the above is true for  $i, k = 1, \dots, n$  when  $x_j := x_{n+j}$  for  $j < 1$ .

cophenetic*Cophenetic Distances for a Hierarchical Clustering*

---

## Description

Computes the cophenetic distances for a hierarchical clustering.

## Usage

```
cophenetic(x)
## Default S3 method:
cophenetic(x)
## S3 method for class 'dendrogram'
cophenetic(x)
```

## Arguments

**x** an R object representing a hierarchical clustering. For the default method, an object of class "[hclust](#)" or with a method for [as.hclust\(\)](#) such as "[agnes](#)" in package [cluster](#).

## Details

The cophenetic distance between two observations that have been clustered is defined to be the intergroup dissimilarity at which the two observations are first combined into a single cluster. Note that this distance has many ties and restrictions.

It can be argued that a dendrogram is an appropriate summary of some data if the correlation between the original distances and the cophenetic distances is high. Otherwise, it should simply be viewed as the description of the output of the clustering algorithm.

`cophenetic` is a generic function. Support for classes which represent hierarchical clusterings (total indexed hierarchies) can be added by providing an [as.hclust\(\)](#) or, more directly, a `cophenetic()` method for such a class.

The method for objects of class "[dendrogram](#)" requires that all leaves of the dendrogram object have non-null labels.

## Value

An object of class "`dist`".

cor

---

*Correlation, Variance and Covariance (Matrices)*

---

## Description

var, cov and cor compute the variance of x and the covariance or correlation of x and y if these are vectors. If x and y are matrices then the covariances (or correlations) between the columns of x and the columns of y are computed.

cov2cor scales a covariance matrix into the corresponding correlation matrix *efficiently*.

## Usage

```
var(x, y = NULL, na.rm = FALSE, use)

cov(x, y = NULL, use = "everything",
    method = c("pearson", "kendall", "spearman"))

cor(x, y = NULL, use = "everything",
    method = c("pearson", "kendall", "spearman"))

cov2cor(V)
```

## Arguments

|       |                                                                                                                                                                                                                                                       |
|-------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| x     | a numeric vector, matrix or data frame.                                                                                                                                                                                                               |
| y     | NULL (default) or a vector, matrix or data frame with compatible dimensions to x. The default is equivalent to y = x (but more efficient).                                                                                                            |
| na.rm | logical. Should missing values be removed?                                                                                                                                                                                                            |
| use   | an optional character string giving a method for computing covariances in the presence of missing values. This must be (an abbreviation of) one of the strings "everything", "all.obs", "complete.obs", "na.or.complete", or "pairwise.complete.obs". |

|        |                                                                                                                                                                          |
|--------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| method | a character string indicating which correlation coefficient (or covariance) is to be computed. One of "pearson" (default), "kendall", or "spearman": can be abbreviated. |
| V      | symmetric numeric matrix, usually positive definite such as a covariance matrix.                                                                                         |

## Details

For cov and cor one must *either* give a matrix or data frame for x *or* give both x and y.

The inputs must be numeric (as determined by `is.numeric`: logical values are also allowed for historical compatibility): the "kendall" and "spearman" methods make sense for ordered inputs but `xtfrm` can be used to find a suitable prior transformation to numbers.

var is just another interface to cov, where na.rm is used to determine the default for use when that is unspecified. If na.rm is TRUE then the complete observations (rows) are used (use = "na.or.complete") to compute the variance. Otherwise, by default use = "everything".

If use is "everything", NAs will propagate conceptually, i.e., a resulting value will be NA whenever one of its contributing observations is NA.

If use is "all.obs", then the presence of missing observations will produce an error. If use is "complete.obs" then missing values are handled by casewise deletion (and if there are no complete cases, that gives an error).

"na.or.complete" is the same unless there are no complete cases, that gives NA. Finally, if use has the value "pairwise.complete.obs" then the correlation or covariance between each pair of variables is computed using all complete pairs of observations on those variables. This can result in covariance or correlation matrices which are not positive semi-definite, as well as NA entries if there are no complete pairs for that pair of variables. For cov and var, "pairwise.complete.obs" only works with the "pearson" method. Note that (the equivalent of) `var(double(0), use = *)` gives NA for use = "everything" and "na.or.complete", and gives an error in the other cases.

The denominator  $n - 1$  is used which gives an unbiased estimator of the (co)variance for i.i.d. observations. These functions return NA when there is only one observation.

For cor(), if method is "kendall" or "spearman", Kendall's  $\tau$  or Spearman's  $\rho$  statistic is used to estimate a rank-based measure of association. These are more robust and have been recommended if the data do not necessarily come from a bivariate normal distribution.

For cov(), a non-Pearson method is unusual but available for the sake of completeness. Note that "spearman" basically computes `cor(R(x), R(y))` (or `cov(., .)`) where  $R(u) := \text{rank}(u, \text{na.last} = \text{"keep"})$ . In the case of missing values, the ranks are calculated depending on the value of use, either based on complete observations, or based on pairwise completeness with reranking for each pair.

When there are ties, Kendall's  $\tau_b$  is computed, as proposed by Kendall (1945).

Scaling a covariance matrix into a correlation one can be achieved in many ways, mathematically most appealing by multiplication with a diagonal matrix from left and right, or more efficiently by using `sweep(., FUN = "/" )` twice. The cov2cor function is even a bit more efficient, and provided mostly for didactical reasons.

## Value

For `r <- cor(*, use = "all.obs")`, it is now guaranteed that `all(abs(r) <= 1)`.

## Note

Some people have noted that the code for Kendall's tau is slow for very large datasets (many more than 1000 cases). It rarely makes sense to do such a computation, but see function `cor.fk` in package **pcaPP**.

range(eigen(C2, only.values = TRUE)$values) # 6.46 1930
C3 <- cov(swM, use = "pairwise")
range(eigen(C3, only.values = TRUE)$values) # 6.19 1938

## Kendall's tau doesn't change much:
symnum(Rc <- cor(swM, method = "kendall", use = "complete"))
symnum(Rp <- cor(swM, method = "kendall", use = "pairwise"))
symnum(R. <- cor(swiss, method = "kendall"))

## "pairwise" is closer componentwise,
summary(abs(c(1 - Rp/R.)))
summary(abs(c(1 - Rc/R.)))

## but "complete" is closer in Eigen space:
EV <- function(m) eigen(m, only.values=TRUE)$values
summary(abs(1 - EV(Rp)/EV(R.)) / abs(1 - EV(Rc)/EV(R.)))

```

cor.test

*Test for Association/Correlation Between Paired Samples***Description**

Test for association between paired samples, using one of Pearson's product moment correlation coefficient, Kendall's  $\tau$  or Spearman's  $\rho$ .

**Usage**

```

cor.test(x, ...)

## Default S3 method:
cor.test(x, y,
         alternative = c("two.sided", "less", "greater"),
         method = c("pearson", "kendall", "spearman"),
         exact = NULL, conf.level = 0.95, continuity = FALSE, ...)

## S3 method for class 'formula'
cor.test(formula, data, subset, na.action, ...)

```

**Arguments**

|             |                                                                                                                                                                                                                   |
|-------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| x, y        | numeric vectors of data values. x and y must have the same length.                                                                                                                                                |
| alternative | indicates the alternative hypothesis and must be one of "two.sided", "greater" or "less". You can specify just the initial letter. "greater" corresponds to positive association, "less" to negative association. |
| method      | a character string indicating which correlation coefficient is to be used for the test. One of "pearson", "kendall", or "spearman", can be abbreviated.                                                           |
| exact       | a logical indicating whether an exact p-value should be computed. Used for Kendall's $\tau$ and Spearman's $\rho$ . See 'Details' for the meaning of NULL (the default).                                          |

|                         |                                                                                                                                                                                                                            |
|-------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>conf.level</code> | confidence level for the returned confidence interval. Currently only used for the Pearson product moment correlation coefficient if there are at least 4 complete pairs of observations.                                  |
| <code>continuity</code> | logical: if true, a continuity correction is used for Kendall's $\tau$ and Spearman's $\rho$ when not computed exactly.                                                                                                    |
| <code>formula</code>    | a formula of the form $\sim u + v$ , where each of $u$ and $v$ are numeric variables giving the data values for one sample. The samples must be of the same length.                                                        |
| <code>data</code>       | an optional matrix or data frame (or similar: see <a href="#">model.frame</a> ) containing the variables in the formula <code>formula</code> . By default the variables are taken from <code>environment(formula)</code> . |
| <code>subset</code>     | an optional vector specifying a subset of observations to be used.                                                                                                                                                         |
| <code>na.action</code>  | a function which indicates what should happen when the data contain NAs. Defaults to <code>getOption("na.action")</code> .                                                                                                 |
| <code>...</code>        | further arguments to be passed to or from methods.                                                                                                                                                                         |

### Details

The three methods each estimate the association between paired samples and compute a test of the value being zero. They use different measures of association, all in the range  $[-1, 1]$  with 0 indicating no association. These are sometimes referred to as tests of no *correlation*, but that term is often confined to the default method.

If method is "pearson", the test statistic is based on Pearson's product moment correlation coefficient `cor(x, y)` and follows a  $t$  distribution with `length(x)-2` degrees of freedom if the samples follow independent normal distributions. If there are at least 4 complete pairs of observation, an asymptotic confidence interval is given based on Fisher's  $Z$  transform.

If method is "kendall" or "spearman", Kendall's  $\tau$  or Spearman's  $\rho$  statistic is used to estimate a rank-based measure of association. These tests may be used if the data do not necessarily come from a bivariate normal distribution.

For Kendall's test, by default (if `exact` is `NULL`), an exact p-value is computed if there are less than 50 paired samples containing finite values and there are no ties. Otherwise, the test statistic is the estimate scaled to zero mean and unit variance, and is approximately normally distributed.

For Spearman's test, p-values are computed using algorithm AS 89 for  $n < 1290$  and `exact = TRUE`, otherwise via the asymptotic  $t$  approximation. Note that these are 'exact' for  $n < 10$ , and use an Edgeworth series approximation for larger sample sizes (the cutoff has been changed from the original paper).

### Value

A list with class "htest" containing the following components:

|                          |                                                                                                              |
|--------------------------|--------------------------------------------------------------------------------------------------------------|
| <code>statistic</code>   | the value of the test statistic.                                                                             |
| <code>parameter</code>   | the degrees of freedom of the test statistic in the case that it follows a $t$ distribution.                 |
| <code>p.value</code>     | the p-value of the test.                                                                                     |
| <code>estimate</code>    | the estimated measure of association, with name "cor", "tau", or "rho" corresponding to the method employed. |
| <code>null.value</code>  | the value of the association measure under the null hypothesis, always 0.                                    |
| <code>alternative</code> | a character string describing the alternative hypothesis.                                                    |

|           |                                                                                                                                                                                       |
|-----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| method    | a character string indicating how the association was measured.                                                                                                                       |
| data.name | a character string giving the names of the data.                                                                                                                                      |
| conf.int  | a confidence interval for the measure of association. Currently only given for Pearson's product moment correlation coefficient in case of at least 4 complete pairs of observations. |

## Formula interface.
require(graphics)
pairs(USJudgeRatings)
cor.test(~ CONT + INTG, data = USJudgeRatings)
```

cov.wt

*Weighted Covariance Matrices***Description**

Returns a list containing estimates of the weighted covariance matrix and the mean of the data, and optionally of the (weighted) correlation matrix.

**Usage**

```
cov.wt(x, wt = rep(1/nrow(x), nrow(x)), cor = FALSE, center = TRUE,
       method = c("unbiased", "ML"))
```

**Arguments**

|        |                                                                                                                                                                                                                                                           |
|--------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| x      | a matrix or data frame. As usual, rows are observations and columns are variables.                                                                                                                                                                        |
| wt     | a non-negative and non-zero vector of weights for each observation. Its length must equal the number of rows of x.                                                                                                                                        |
| cor    | a logical indicating whether the estimated correlation weighted matrix will be returned as well.                                                                                                                                                          |
| center | either a logical or a numeric vector specifying the centers to be used when computing covariances. If TRUE, the (weighted) mean of each variable is used, if FALSE, zero is used. If center is numeric, its length must equal the number of columns of x. |
| method | string specifying how the result is scaled, see ‘Details’ below. Can be abbreviated.                                                                                                                                                                      |

**Details**

By default, method = "unbiased", The covariance matrix is divided by one minus the sum of squares of the weights, so if the weights are the default ( $1/n$ ) the conventional unbiased estimate of the covariance matrix with divisor  $(n - 1)$  is obtained.

**Value**

A list containing the following named components:

|        |                                                                            |
|--------|----------------------------------------------------------------------------|
| cov    | the estimated (weighted) covariance matrix                                 |
| center | an estimate for the center (mean) of the data.                             |
| n.obs  | the number of observations (rows) in x.                                    |
| wt     | the weights used in the estimation. Only returned if given as an argument. |
| cor    | the estimated correlation matrix. Only returned if cor is TRUE.            |

**See Also**

[cov](#) and [var](#).

**Examples**

```
(xy <- cbind(x = 1:10, y = c(1:3, 8:5, 8:10)))
w1 <- c(0,0,0,1,1,1,1,1,0,0)
cov.wt(xy, wt = w1) # i.e. method = "unbiased"
cov.wt(xy, wt = w1, method = "ML", cor = TRUE)
```

cpgram

*Plot Cumulative Periodogram***Description**

Plots a cumulative periodogram.

**Usage**

```
cpgram(ts, taper = 0.1,
       main = paste("Series: ", deparse1(substitute(ts))),
       ci.col = "blue")
```

**Arguments**

|        |                                               |
|--------|-----------------------------------------------|
| ts     | a univariate time series                      |
| taper  | proportion tapered in forming the periodogram |
| main   | main title                                    |
| ci.col | colour for confidence band.                   |

**Value**

None.

**Side Effects**

Plots the cumulative periodogram in a square plot.

**Note**

From package **MASS**.

**Author(s)**

B.D. Ripley

**Examples**

```
require(graphics)

par(pty = "s", mfrow = c(1,2))
cpgram(lh)
lh.ar <- ar(lh, order.max = 9)
cpgram(lh.ar$resid, main = "AR(3) fit to lh")

cpgram(ldeaths)
```

cutree

*Cut a Tree into Groups of Data***Description**

Cuts a tree, e.g., as resulting from [hclust](#), into several groups either by specifying the desired number(s) of groups or the cut height(s).

**Usage**

```
cutree(tree, k = NULL, h = NULL)
```

**Arguments**

|      |                                                                                                                                                     |
|------|-----------------------------------------------------------------------------------------------------------------------------------------------------|
| tree | a tree as produced by <a href="#">hclust</a> . cutree() only expects a list with components merge, height, and labels, of appropriate content each. |
| k    | an integer scalar or vector with the desired number of groups                                                                                       |
| h    | numeric scalar or vector with heights where the tree should be cut.                                                                                 |

At least one of k or h must be specified, k overrides h if both are given.

**Details**

Cutting trees at a given height is only possible for ultrametric trees (with monotone clustering heights).

**Value**

cutree returns a vector with group memberships if k or h are scalar, otherwise a matrix with group memberships is returned where each column corresponds to the elements of k or h, respectively (which are also used as column names).

**References**

Becker, R. A., Chambers, J. M. and Wilks, A. R. (1988) *The New S Language*. Wadsworth & Brooks/Cole.

**See Also**

[hclust](#), [dendrogram](#) for cutting trees themselves.

**Examples**

```
hc <- hclust(dist(USArrests))

cutree(hc, k = 1:5) #k = 1 is trivial
cutree(hc, h = 250)

## Compare the 2 and 4 grouping:
g24 <- cutree(hc, k = c(2,4))
table(grp2 = g24[, "2"], grp4 = g24[, "4"])
```

decompose

*Classical Seasonal Decomposition by Moving Averages***Description**

Decompose a time series into seasonal, trend and irregular components using moving averages. Deals with additive or multiplicative seasonal component.

**Usage**

```
decompose(x, type = c("additive", "multiplicative"), filter = NULL)
```

**Arguments**

|        |                                                                                                                                                                                                    |
|--------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| x      | A time series.                                                                                                                                                                                     |
| type   | The type of seasonal component. Can be abbreviated.                                                                                                                                                |
| filter | A vector of filter coefficients in reverse time order (as for AR or MA coefficients), used for filtering out the seasonal component. If NULL, a moving average with symmetric window is performed. |

**Details**

The additive model used is:

$$Y_t = T_t + S_t + e_t$$

The multiplicative model used is:

$$Y_t = T_t S_t e_t$$

The function first determines the trend component using a moving average (if filter is NULL, a symmetric window with equal weights is used), and removes it from the time series. Then, the seasonal figure is computed by averaging, for each time unit, over all periods. The seasonal figure is then centered. Finally, the error component is determined by removing trend and seasonal figure (recycled as needed) from the original time series.

This only works well if x covers an integer number of complete periods.

**Value**

An object of class "decomposed.ts" with following components:

|          |                                                              |
|----------|--------------------------------------------------------------|
| x        | The original series.                                         |
| seasonal | The seasonal component (i.e., the repeated seasonal figure). |
| figure   | The estimated seasonal figure only.                          |
| trend    | The trend component.                                         |
| random   | The remainder part.                                          |
| type     | The value of type.                                           |

**Note**

The function [stl](#) provides a much more sophisticated decomposition.

x <- ts(x, start = c(1951, 1), end = c(1958, 4), frequency = 4)
m <- decompose(x)
## seasonal figure: 6.25, 8.62, -8.84, -6.03
round(decompose(x)$figure / 10, 2)
```

---

delete.response

*Modify Terms Objects*

---

**Description**

`delete.response` returns a terms object for the same model but with no response variable.

`drop.terms` removes terms from the right-hand side of the model, optionally keeping the response. There is also a `[.terms` method performing a complementary operation: it extracts terms, always keeping the response.

`reformulate` creates a formula from a character vector. If `length(termlabels) > 1`, its elements are concatenated with `+`. Non-syntactic names (e.g. containing spaces or special characters; see [make.names](#)) must be protected with backticks (see examples). A non-`parseable` response still works for now, back compatibly, with a deprecation warning.

**Usage**

```
delete.response(termobj)

reformulate(termlabels, response = NULL, intercept = TRUE, env = parent.frame())

drop.terms(termobj, dropx = NULL, keep.response = FALSE)

## S3 method for class 'terms'
termobj[i]
```

**Arguments**

|                            |                                                                                                                                                                                                                                                                                                          |
|----------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>termobj</code>       | a <a href="#">terms</a> object.                                                                                                                                                                                                                                                                          |
| <code>term.labels</code>   | character vector giving the right-hand side of a model formula. May be zero-length.                                                                                                                                                                                                                      |
| <code>response</code>      | a character string, symbol or call giving the left-hand side of a model formula, or NULL.                                                                                                                                                                                                                |
| <code>intercept</code>     | logical: should the formula have an intercept?                                                                                                                                                                                                                                                           |
| <code>env</code>           | the <a href="#">environment</a> of the <a href="#">formula</a> returned.                                                                                                                                                                                                                                 |
| <code>dropx, i</code>      | a numeric vector indexing <code>labels(termobj)</code> (that is, the "term.labels" attribute of <code>termobj</code> ), indicating terms to drop ( <code>dropx</code> ) or select ( <code>i</code> ) from the right-hand side of the model. The default <code>dropx=NULL</code> means to keep all terms. |
| <code>keep.response</code> | logical: keep the response in the resulting object?                                                                                                                                                                                                                                                      |

**Value**

`delete.response` and `drop.terms` return a [terms](#) object.

`reformulate` returns a [formula](#).

**See Also**

[terms](#)

**Examples**

```
ff <- y ~ z + x + w
tt <- terms(ff)
tt
delete.response(tt)
drop.terms(tt, 2:3, keep.response = TRUE)
tt[-1]
tt[2:3]
reformulate(attr(tt, "term.labels"))

## keep LHS :
reformulate("x*w", ff[[2]])
fS <- surv(ft, case) ~ a + b
reformulate(c("a", "b*f"), fS[[2]])

## using non-syntactic names:
reformulate(c("`P/E`", "`% Growth`"), response = as.name("+"))

x <- c("a name", "another name")
tryCatch( reformulate(x), error = function(e) "Syntax error." )
## rather backquote the strings in x :
reformulate(sprintf("`%s`", x))

stopifnot(identical(      ~ var, reformulate("var")),
           identical(~ a + b + c, reformulate(letters[1:3])),
           identical( y ~ a + b, reformulate(letters[1:2], "y"))
          )
```

dendrapply

*Apply a Function to All Nodes of a Dendrogram***Description**

Apply function FUN to each node of a [dendrogram](#) recursively. When `y <- dendrapply(x, fn)`, then `y` is a dendrogram of the same graph structure as `x` and for each node, `y.node[j] <- FUN(x.node[j], ...)` (where `y.node[j]` is an (invalid!) notation for the `j`-th node of `y`).

**Usage**

```
dendrapply(X, FUN, ...)
```

**Arguments**

|                  |                                                                                                                                                                |
|------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>X</code>   | an object of class " <a href="#">dendrogram</a> ".                                                                                                             |
| <code>FUN</code> | an R function to be applied to each dendrogram node, typically working on its <a href="#">attributes</a> alone, returning an altered version of the same node. |
| <code>...</code> | potential further arguments passed to FUN.                                                                                                                     |

**Value**

Usually a dendrogram of the same (graph) structure as `X`. For that, the function must be conceptually of the form `FUN <- function(X) { attributes(X) <- .....; X }`, i.e., returning the node with some attributes added or changed.

**Note**

The implementation is somewhat experimental and suggestions for enhancements (or nice examples of usage) are very welcome. The current implementation is *recursive* and inefficient for dendrograms with many non-leaves. See the ‘Warning’ in [dendrogram](#).

**Author(s)**

Martin Maechler

**See Also**

[as.dendrogram](#), [lapply](#) for applying a function to each component of a list, [rapply](#) for doing so to each non-list component of a nested list.

**Examples**

```
require(graphics)

## a smallish simple dendrogram
dhc <- as.dendrogram(hc <- hclust(dist(USArrests), "ave"))
(dhc21 <- dhc[[2]][[1]])

## too simple:
dendrapply(dhc21, function(n) utils::str(attributes(n)))
```

```
## toy example to set colored leaf labels :
local({
  collab <- function(n) {
    if(is.leaf(n)) {
      a <- attributes(n)
      i <- i+1
      attr(n, "nodePar") <-
        c(a$nodePar, list(lab.col = mycols[i], lab.font = i%%3))
    }
    n
  }
  mycols <- grDevices::rainbow(attr(dhc21, "members"))
  i <- 0
})
dL <- dendrapply(dhc21, collab)
op <- par(mfrow = 2:1)
plot(dhc21)
plot(dL) ## --> colored labels!
par(op)
```

---

dendrogram

*General Tree Structures*

---

## Description

Class "dendrogram" provides general functions for handling tree-like structures. It is intended as a replacement for similar functions in hierarchical clustering and classification/regression trees, such that all of these can use the same engine for plotting or cutting trees.

## Usage

```
as.dendrogram(object, ...)
## S3 method for class 'hclust'
as.dendrogram(object, hang = -1, check = TRUE, ...)

## S3 method for class 'dendrogram'
as.hclust(x, ...)

## S3 method for class 'dendrogram'
plot(x, type = c("rectangle", "triangle"),
      center = FALSE,
      edge.root = is.leaf(x) || !is.null(attr(x, "edgetext")),
      nodePar = NULL, edgePar = list(),
      leaflab = c("perpendicular", "textlike", "none"),
      dLeaf = NULL, xlab = "", ylab = "", xaxt = "n", yaxt = "s",
      horiz = FALSE, frame.plot = FALSE, xlim, ylim, ...)

## S3 method for class 'dendrogram'
cut(x, h, ...)

## S3 method for class 'dendrogram'
merge(x, y, ..., height,
```

```

adjust = c("auto", "add.max", "none"))

## S3 method for class 'dendrogram'
nobs(object, ...)

## S3 method for class 'dendrogram'
print(x, digits, ...)

## S3 method for class 'dendrogram'
rev(x)

## S3 method for class 'dendrogram'
str(object, max.level = NA, digits.d = 3,
     give.attr = FALSE, wid = getOption("width"),
     nest.lev = 0, indent.str = "",
     last.str = getOption("str.dendrogram.last"), stem = "--",
     ...)

is.leaf(object)

```

### Arguments

|           |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|-----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| object    | any R object that can be made into one of class "dendrogram".                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| x, y      | object(s) of class "dendrogram".                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| hang      | numeric scalar indicating how the <i>height</i> of leaves should be computed from the heights of their parents; see <a href="#">plot.hclust</a> .                                                                                                                                                                                                                                                                                                                                                                                           |
| check     | logical indicating if object should be checked for validity. This check is not necessary when x is known to be valid such as when it is the direct result of <code>hclust()</code> . The default is <code>check=TRUE</code> , e.g. for protecting against memory explosion with invalid inputs.                                                                                                                                                                                                                                             |
| type      | type of plot.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| center    | logical; if TRUE, nodes are plotted centered with respect to the leaves in the branch. Otherwise (default), plot them in the middle of all direct child nodes.                                                                                                                                                                                                                                                                                                                                                                              |
| edge.root | logical; if true, draw an edge to the root node.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| nodePar   | a list of plotting parameters to use for the nodes (see <a href="#">points</a> ) or NULL by default which does not draw symbols at the nodes. The list may contain components named <code>pch</code> , <code>cex</code> , <code>col</code> , <code>xpd</code> , and/or <code>bg</code> each of which can have length two for specifying separate attributes for <i>inner</i> nodes and <i>leaves</i> . Note that the default of <code>pch</code> is 1:2, so you may want to use <code>pch = NA</code> if you specify <code>nodePar</code> . |
| edgePar   | a list of plotting parameters to use for the edge <a href="#">segments</a> and labels (if there's an <code>edgetext</code> ). The list may contain components named <code>col</code> , <code>lty</code> and <code>lwd</code> (for the segments), <code>p.col</code> , <code>p.lwd</code> , and <code>p.lty</code> (for the <a href="#">polygon</a> around the text) and <code>t.col</code> for the text color. As with <code>nodePar</code> , each can have length two for differentiating leaves and inner nodes.                          |
| leaflab   | a string specifying how leaves are labeled. The default "perpendicular" write text vertically (by default).<br>"textlike" writes text horizontally (in a rectangle), and<br>"none" suppresses leaf labels.                                                                                                                                                                                                                                                                                                                                  |
| dLeaf     | a number specifying the distance in user coordinates between the tip of a leaf and its label. If NULL as per default, 3/4 of a letter width or height is used.                                                                                                                                                                                                                                                                                                                                                                              |

|                                                                        |                                                                                                                                                                                                                                                                                                                                                                                  |
|------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>horiz</code>                                                     | logical indicating if the dendrogram should be drawn <i>horizontally</i> or not.                                                                                                                                                                                                                                                                                                 |
| <code>frame.plot</code>                                                | logical indicating if a box around the plot should be drawn, see <a href="#">plot.default</a> .                                                                                                                                                                                                                                                                                  |
| <code>h</code>                                                         | height at which the tree is cut.                                                                                                                                                                                                                                                                                                                                                 |
| <code>height</code>                                                    | height at which the two dendrograms should be merged. If not specified (or <code>NULL</code> ), the default is ten percent larger than the (larger of the) two component heights.                                                                                                                                                                                                |
| <code>adjust</code>                                                    | a string determining if the leaf values should be adjusted. The default, "auto", checks if the (first) two dendrograms both start at 1; if they do, "add.max" is chosen, which adds the maximum of the previous dendrogram leaf values to each leaf of the "next" dendrogram. Specifying <code>adjust</code> to another value skips the check and hence is a tad more efficient. |
| <code>xlim, ylim</code>                                                | optional x- and y-limits of the plot, passed to <a href="#">plot.default</a> . The defaults for these show the full dendrogram.                                                                                                                                                                                                                                                  |
| <code>..., xlab, ylab, xaxt, yaxt</code>                               | graphical parameters, or arguments for other methods.                                                                                                                                                                                                                                                                                                                            |
| <code>digits</code>                                                    | integer specifying the precision for printing, see <a href="#">print.default</a> .                                                                                                                                                                                                                                                                                               |
| <code>max.level, digits.d, give.attr, wid, nest.lev, indent.str</code> | arguments to <code>str</code> , see <a href="#">str.default()</a> . Note that <code>give.attr = FALSE</code> still shows height and members attributes for each node.                                                                                                                                                                                                            |
| <code>last.str, stem</code>                                            | strings used for <code>str()</code> specifying how the last branch (at each level) should start and the <i>stem</i> to use for each dendrogram branch. In some environments, using <code>last.str = ""</code> will provide much nicer looking output, than the historical default <code>last.str = "~"</code> .                                                                  |

## Details

The dendrogram is directly represented as a nested list where each component corresponds to a branch of the tree. Hence, the first branch of tree `z` is `z[[1]]`, the second branch of the corresponding subtree is `z[[1]][[2]]`, or shorter `z[[c(1,2)]]`, etc.. Each node of the tree carries some information needed for efficient plotting or cutting as attributes, of which only `members`, `height` and `leaf` for leaves are compulsory:

`members` total number of leaves in the branch

`height` numeric non-negative height at which the node is plotted.

`midpoint` numeric horizontal distance of the node from the left border (the leftmost leaf) of the branch (unit 1 between all leaves). This is used for `plot(*, center = FALSE)`.

`label` character; the label of the node

`x.member` for `cut()`\$upper, the number of *former* members; more generally a substitute for the `members` component used for 'horizontal' (when `horiz = FALSE`, else 'vertical') alignment.

`edgetext` character; the label for the edge leading to the node

`nodePar` a named list (of length-1 components) specifying node-specific attributes for [points](#) plotting, see the `nodePar` argument above.

`edgePar` a named list (of length-1 components) specifying attributes for [segments](#) plotting of the edge leading to the node, and drawing of the `edgetext` if available, see the `edgePar` argument above.

`leaf` logical, if `TRUE`, the node is a leaf of the tree.

`cut.dendrogram()` returns a list with components `$upper` and `$lower`, the first is a truncated version of the original tree, also of class `dendrogram`, the latter a list with the branches obtained from cutting the tree, each a `dendrogram`.

There are `[[`, `print`, and `str` methods for "dendrogram" objects where the first one (extraction) ensures that selecting sub-branches keeps the class, i.e., returns a `dendrogram` even if only a leaf. On the other hand, `[` (*single bracket*) extraction returns the underlying list structure.

Objects of class "hclust" can be converted to class "dendrogram" using method `as.dendrogram()`, and since R 2.13.0, there is also a `as.hclust()` method as an inverse.

`rev.dendrogram` simply returns the dendrogram `x` with reversed nodes, see also `reorder.dendrogram`.

The `merge(x, y, ...)` method merges two or more dendrograms into a new one which has `x` and `y` (and optional further arguments) as branches. Note that before R 3.1.2, `adjust = "none"` was used implicitly, which is invalid when, e.g., the dendrograms are from `as.dendrogram(hclust(...))`.

`nobs(object)` returns the total number of leaves (the member's attribute, see above).

`is.leaf(object)` returns logical indicating if object is a leaf (the most simple dendrogram).

`plotNode()` and `plotNodeLimit()` are helper functions.

### Warning

Some operations on dendrograms such as `merge()` make use of recursion. For deep trees it may be necessary to increase `options("expressions")`: if you do, you are likely to need to set the C stack size (`Cstack_info()[["size"]]`) larger than the default where possible.

### Note

`plot()`: When using `type = "triangle"`, `center = TRUE` often looks better.

`str(d)`: If you really want to see the *internal* structure, use `str(unclass(d))` instead.

### See Also

`dendrapply` for applying a function to *each* node. `order.dendrogram` and `reorder.dendrogram`; further, the `labels` method.

### Examples

```
require(graphics); require(utils)

hc <- hclust(dist(USArrests), "ave")
(dend1 <- as.dendrogram(hc)) # "print()" method
str(dend1)                  # "str()" method
str(dend1, max.level = 2, last.str = "'") # only the first two sub-levels
oo <- options(str.dendrogram.last = "\\") # yet another possibility
str(dend1, max.level = 2) # only the first two sub-levels
options(oo) # .. resetting them

op <- par(mfrow = c(2,2), mar = c(5,2,1,4))
plot(dend1)
## "triangle" type and show inner nodes:
plot(dend1, nodePar = list(pch = c(1,NA), cex = 0.8, lab.cex = 0.8),
     type = "t", center = TRUE)
plot(dend1, edgePar = list(col = 1:2, lty = 2:3),
     dLeaf = 1, edge.root = TRUE)
```

```

plot(dend1, nodePar = list(pch = 2:1, cex = .4*2:1, col = 2:3),
     horiz = TRUE)

## simple test for as.hclust() as the inverse of as.dendrogram():
stopifnot(identical(as.hclust(dend1)[1:4], hc[1:4]))

dend2 <- cut(dend1, h = 70)
## leaves are wrong horizontally in R 4.0 and earlier:
plot(dend2$upper)
plot(dend2$upper, nodePar = list(pch = c(1,7), col = 2:1))
## dend2$lower is *NOT* a dendrogram, but a list of .. :
plot(dend2$lower[[3]], nodePar = list(col = 4), horiz = TRUE, type = "tr")
## "inner" and "leaf" edges in different type & color :
plot(dend2$lower[[2]], nodePar = list(col = 1), # non empty list
     edgePar = list(lty = 1:2, col = 2:1), edge.root = TRUE)
par(op)
d3 <- dend2$lower[[2]][[2]][[1]]
stopifnot(identical(d3, dend2$lower[[2]][[c(2,1)]]))
str(d3, last.str = "")

## to peek at the inner structure "if you must", use '[' indexing :
str(d3[2][[1]]) ## or the full
str(d3[])

## merge() to join dendrograms:
(d13 <- merge(dend2$lower[[1]], dend2$lower[[3]]))
## merge() all parts back (using default 'height' instead of original one):
den.1 <- Reduce(merge, dend2$lower)
## or merge() all four parts at same height --> 4 branches (!)
d. <- merge(dend2$lower[[1]], dend2$lower[[2]], dend2$lower[[3]],
            dend2$lower[[4]])
## (with a warning) or the same using do.call :
stopifnot(identical(d., do.call(merge, dend2$lower)))
plot(d., main = "merge(d1, d2, d3, d4) |-> dendrogram with a 4-split")

## "Zoom" in to the first dendrogram :
plot(dend1, xlim = c(1,20), ylim = c(1,50))

nP <- list(col = 3:2, cex = c(2.0, 0.75), pch = 21:22,
          bg = c("light blue", "pink"),
          lab.cex = 0.75, lab.col = "tomato")
plot(d3, nodePar = nP, edgePar = list(col = "gray", lwd = 2), horiz = TRUE)
addE <- function(n) {
  if(!is.leaf(n)) {
    attr(n, "edgePar") <- list(p.col = "plum")
    attr(n, "edgetext") <- paste(attr(n, "members"), "members")
  }
  n
}

```

## Description

The (S3) generic function `density` computes kernel density estimates. Its default method does so with the given kernel and bandwidth for univariate observations.

## Usage

```
density(x, ...)
## Default S3 method:
density(x, bw = "nrd0", adjust = 1,
        kernel = c("gaussian", "epanechnikov", "rectangular",
                    "triangular", "biweight",
                    "cosine", "optcosine"),
        weights = NULL, window = kernel, width,
        give.Rkern = FALSE, subdensity = FALSE,
        warnWbw = var(weights) > 0,
        n = 512, from, to, cut = 3, ext = 4,
        old.coords = FALSE,
        na.rm = FALSE, ...)
```

## Arguments

- |                |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|----------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| x              | the data from which the estimate is to be computed. For the default method a numeric vector: long vectors are not supported.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| bw             | <p>the smoothing bandwidth to be used. The kernels are scaled such that this is the standard deviation of the smoothing kernel. (Note this differs from the reference books cited below.)</p> <p>bw can also be a character string giving a rule to choose the bandwidth. See <a href="#">bw.nrd</a>.</p> <p>The default, "nrd0", has remained the default for historical and compatibility reasons, rather than as a general recommendation, where e.g., "SJ" would rather fit, see also Venables and Ripley (2002).</p> <p>The specified (or computed) value of bw is multiplied by adjust.</p>                                                                                                                 |
| adjust         | the bandwidth used is actually <code>adjust*bw</code> . This makes it easy to specify values like 'half the default' bandwidth.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| kernel, window | <p>a character string giving the smoothing kernel to be used. This must partially match one of "gaussian", "rectangular", "triangular", "epanechnikov", "biweight", "cosine" or "optcosine", with default "gaussian", and may be abbreviated to a unique prefix (single letter).</p> <p>"cosine" is smoother than "optcosine", which is the usual 'cosine' kernel in the literature and almost MSE-efficient. However, "cosine" is the version used by S.</p>                                                                                                                                                                                                                                                     |
| weights        | <p>numeric vector of non-negative observation weights, hence of same length as x. The default NULL is equivalent to <code>weights = rep(1/nx, nx)</code> where nx is the length of (the finite entries of) <code>x[]</code>. If <code>na.rm = TRUE</code> and there are NA's in x, they <i>and</i> the corresponding weights are removed before computations. In that case, when the original weights have summed to one, they are re-scaled to keep doing so.</p> <p>Note that weights are <i>not</i> taken into account for automatic bandwidth rules, i.e., when bw is a string. When the weights are proportional to true counts cn, <code>density(x = rep(x, cn))</code> may be used instead of weights.</p> |

|            |                                                                                                                                                                                                                                                                                                                                                            |
|------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| width      | this exists for compatibility with S; if given, and bw is not, will set bw to width if this is a character string, or to a kernel-dependent multiple of width if this is numeric.                                                                                                                                                                          |
| give.Rkern | logical; if true, <i>no</i> density is estimated, and the ‘canonical bandwidth’ of the chosen kernel is returned instead.                                                                                                                                                                                                                                  |
| subdensity | used only when weights are specified which do not sum to one. When true, it indicates that a “sub-density” is desired and no warning should be signalled. By default, when false, a <b>warning</b> is signalled when the weights do not sum to one.                                                                                                        |
| warnWbw    | <b>logical</b> , used only when weights are specified <i>and</i> bw is character, i.e., automatic bandwidth selection is chosen (as by default). When true (as by default), a <b>warning</b> is signalled to alert the user that automatic bandwidth selection will not take the weights into account and hence may be suboptimal.                         |
| n          | the number of equally spaced points at which the density is to be estimated. When $n > 512$ , it is rounded up to a power of 2 during the calculations (as <b>fft</b> is used) and the final result is interpolated by <b>approx</b> . So it almost always makes sense to specify n as a power of two.                                                     |
| from, to   | the left and right-most points of the grid at which the density is to be estimated; the defaults are $\text{cut} * \text{bw}$ outside of $\text{range}(x)$ .                                                                                                                                                                                               |
| cut        | by default, the values of from and to are cut bandwidths beyond the extremes of the data. This allows the estimated density to drop to approximately zero at the extremes.                                                                                                                                                                                 |
| ext        | a positive extension factor, 4 by default. The values from and to are further extended on both sides to $\text{lo} <- \text{from} - \text{ext} * \text{bw}$ and $\text{up} <- \text{to} + \text{ext} * \text{bw}$ which are then used to build the grid used for the FFT and interpolation, see n above. Do not change unless you know what you are doing! |
| old.coords | <b>logical</b> to require pre-R 4.4.0 behaviour which gives too large values by a factor of about $(1 + 1/(2n - 2))$ .                                                                                                                                                                                                                                     |
| na.rm      | logical; if TRUE, missing values are removed from x. If FALSE any missing values cause an error.                                                                                                                                                                                                                                                           |
| ...        | further arguments for (non-default) methods.                                                                                                                                                                                                                                                                                                               |

### Details

The algorithm used in `density.default` disperses the mass of the empirical distribution function over a regular grid of at least 512 points and then uses the fast Fourier transform to convolve this approximation with a discretized version of the kernel and then uses linear approximation to evaluate the density at the specified points.

The statistical properties of a kernel are determined by  $\sigma_K^2 = \int t^2 K(t) dt$  which is always  $= 1$  for our kernels (and hence the bandwidth bw is the standard deviation of the kernel) and  $R(K) = \int K^2(t) dt$ .

MSE-equivalent bandwidths (for different kernels) are proportional to  $\sigma_K R(K)$  which is scale invariant and for our kernels equal to  $R(K)$ . This value is returned when `give.Rkern = TRUE`. See the examples for using exact equivalent bandwidths.

Infinite values in x are assumed to correspond to a point mass at  $\pm \text{Inf}$  and the density estimate is of the sub-density on  $(-\text{Inf}, +\text{Inf})$ .

### Value

If `give.Rkern` is true, the number  $R(K)$ , otherwise an object with class “density” whose underlying structure is a list containing the following components.

|           |                                                                            |
|-----------|----------------------------------------------------------------------------|
| x         | the n coordinates of the points where the density is estimated.            |
| y         | the estimated density values. These will be non-negative, but can be zero. |
| bw        | the bandwidth used.                                                        |
| n         | the sample size after elimination of missing values.                       |
| call      | the call which produced the result.                                        |
| data.name | the deparsed name of the x argument.                                       |
| has.na    | logical, for compatibility (always FALSE).                                 |

The print method reports [summary](#) values on the x and y components.

  lines(density(precip, bw = bw, adjust = h.f[i], kernel = kernels[i]),
        col = i)
legend(55, 0.035, legend = kernels, col = seq(kernels), lty = 1)
```

deriv

*Symbolic and Algorithmic Derivatives of Simple Expressions*

## Description

Compute derivatives of simple expressions, symbolically and algorithmically.

## Usage

```
D (expr, name)
deriv(expr, ...)
deriv3(expr, ...)

## Default S3 method:
deriv(expr, namevec, function.arg = NULL, tag = ".expr",
      hessian = FALSE, ...)
## S3 method for class 'formula'
deriv(expr, namevec, function.arg = NULL, tag = ".expr",
      hessian = FALSE, ...)

## Default S3 method:
deriv3(expr, namevec, function.arg = NULL, tag = ".expr",
       hessian = TRUE, ...)
## S3 method for class 'formula'
deriv3(expr, namevec, function.arg = NULL, tag = ".expr",
       hessian = TRUE, ...)
```

## Arguments

|                            |                                                                                                                                                                                                                           |
|----------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>expr</code>          | a <a href="#">expression</a> or <a href="#">call</a> or (except <code>D</code> ) a formula with no lhs.                                                                                                                   |
| <code>name, namevec</code> | character vector, giving the variable names (only one for <code>D()</code> ) with respect to which derivatives will be computed.                                                                                          |
| <code>function.arg</code>  | if specified and non-NULL, a character vector of arguments for a function return, or a function (with empty body) or TRUE, the latter indicating that a function with argument names <code>namevec</code> should be used. |
| <code>tag</code>           | character; the prefix to be used for the locally created variables in result. Must be no longer than 60 bytes when translated to the native encoding.                                                                     |
| <code>hessian</code>       | a logical value indicating whether the second derivatives should be calculated and incorporated in the return value.                                                                                                      |
| <code>...</code>           | arguments to be passed to or from methods.                                                                                                                                                                                |

## Details

D is modelled after its S namesake for taking simple symbolic derivatives.

deriv is a *generic* function with a default and a [formula](#) method. It returns a [call](#) for computing the expr and its (partial) derivatives, simultaneously. It uses so-called *algorithmic derivatives*. If function.arg is a function, its arguments can have default values, see the fx example below.

Currently, deriv.formula just calls deriv.default after extracting the expression to the right of ~.

deriv3 and its methods are equivalent to deriv and its methods except that hessian defaults to TRUE for deriv3.

The internal code knows about the arithmetic operators +, -, \*, / and ^, and the single-variable functions exp, log, sin, cos, tan, sinh, cosh, sqrt, pnorm, dnorm, asin, acos, atan, gamma, lgamma, digamma and trigamma, as well as psigamma for one or two arguments (but derivative only with respect to the first). (Note that only the standard normal distribution is considered.)

Since R 3.4.0, the single-variable functions [log1p](#), [expm1](#), [log2](#), [log10](#), [cospi](#), [sinpi](#), [tanpi](#), [factorial](#), and [lfactorial](#) are supported as well.

## Value

D returns a call and therefore can easily be iterated for higher derivatives.

deriv and deriv3 normally return an [expression](#) object whose evaluation returns the function values with a "gradient" attribute containing the gradient matrix. If hessian is TRUE the evaluation also returns a "hessian" attribute containing the Hessian array.

If function.arg is not NULL, deriv and deriv3 return a function with those arguments rather than an expression.

## Examples

```
## formula argument :
dx2x <- deriv(~ x^2, "x") ; dx2x
## Not run: expression({
  .value <- x^2
  .grad <- array(0, c(length(.value), 1), list(NULL, c("x")))
  .grad[, "x"] <- 2 * x
  attr(.value, "gradient") <- .grad
  .value
})
## End(Not run)
mode(dx2x)
x <- -1:2
eval(dx2x)
```

```

## Something 'tougher':
trig.exp <- expression(sin(cos(x + y^2)))
( D.sc <- D(trig.exp, "x") )
all.equal(D(trig.exp[[1]], "x"), D.sc)

( dxy <- deriv(trig.exp, c("x", "y")) )
y <- 1
eval(dxy)
eval(D.sc)

## function returned:
deriv((y ~ sin(cos(x) * y)), c("x","y"), function.arg = TRUE)

## function with defaulted arguments:
(fx <- deriv(y ~ b0 + b1 * 2^(-x/th), c("b0", "b1", "th"),
            function(b0, b1, th, x = 1:7){} ) )
fx(2, 3, 4)

## First derivative

D(expression(x^2), "x")
stopifnot(D(as.name("x"), "x") == 1)

## Higher derivatives
deriv3(y ~ b0 + b1 * 2^(-x/th), c("b0", "b1", "th"),
      c("b0", "b1", "th", "x") )

## Higher derivatives:
DD <- function(expr, name, order = 1) {
  if(order < 1) stop("'order' must be >= 1")
  if(order == 1) D(expr, name)
  else DD(D(expr, name), name, order - 1)
}
DD(expression(sin(x^2)), "x", 3)
## showing the limits of the internal "simplify()" :
## Not run:
-sin(x^2) * (2 * x) * 2 + ((cos(x^2) * (2 * x) * (2 * x) + sin(x^2) *
  2) * (2 * x) + sin(x^2) * (2 * x) * 2)

## End(Not run)

## New (R 3.4.0, 2017):
D(quote(log1p(x^2)), "x") ## log1p(x) = log(1 + x)
stopifnot(identical(
  D(quote(log1p(x^2)), "x"),
  D(quote(log(1+x^2)), "x")))
D(quote(expm1(x^2)), "x") ## expm1(x) = exp(x) - 1
stopifnot(identical(
  D(quote(expm1(x^2)), "x") -> Dex1,
  D(quote(exp(x^2)-1), "x"),
  identical(Dex1, quote(exp(x^2) * (2 * x)))))

D(quote(sinpi(x^2)), "x") ## sinpi(x) = sin(pi*x)
D(quote(cospi(x^2)), "x") ## cospi(x) = cos(pi*x)
D(quote(tanpi(x^2)), "x") ## tanpi(x) = tan(pi*x)

stopifnot(identical(D(quote(log2 (x^2)), "x"),

```

```
quote(2 * x/(x^2 * log(2)))),  
identical(D(quote(log10(x^2)), "x"),  
quote(2 * x/(x^2 * log(10)))))
```

|          |                       |
|----------|-----------------------|
| deviance | <i>Model Deviance</i> |
|----------|-----------------------|

---

**Description**

Returns the deviance of a fitted model object.

**Usage**

```
deviance(object, ...)
```

**Arguments**

- object            an object for which the deviance is desired.
- ...              additional optional argument.

**Details**

This is a generic function which can be used to extract deviances for fitted models. Consult the individual modeling functions for details on how to use this function.

**Value**

The value of the deviance extracted from the object object.

**References**

Chambers, J. M. and Hastie, T. J. (1992) *Statistical Models in S*. Wadsworth & Brooks/Cole.

**See Also**

|-------------|------------------------------------|
| df.residual | <i>Residual Degrees-of-Freedom</i> |
|-------------|------------------------------------|

---

**Description**

Returns the residual degrees-of-freedom extracted from a fitted model object.

**Usage**

```
df.residual(object, ...)
```

**Arguments**

|        |                                                         |
|--------|---------------------------------------------------------|
| object | an object for which the degrees-of-freedom are desired. |
| ...    | additional optional arguments.                          |

**Details**

This is a generic function which can be used to extract residual degrees-of-freedom for fitted models. Consult the individual modeling functions for details on how to use this function.

The default method just extracts the `df.residual` component.

**Value**

The value of the residual degrees-of-freedom extracted from the object `x`.

**See Also**

---

diffinv

*Discrete Integration: Inverse of Differencing*

---

**Description**

Computes the inverse function of the lagged differences function [diff](#).

**Usage**

```
diffinv(x, ...)

## Default S3 method:
diffinv(x, lag = 1, differences = 1, xi, ...)
## S3 method for class 'ts'
diffinv(x, lag = 1, differences = 1, xi, ...)
```

**Arguments**

|             |                                                                                                                       |
|-------------|-----------------------------------------------------------------------------------------------------------------------|
| x           | a numeric vector, matrix, or time series.                                                                             |
| lag         | a scalar lag parameter.                                                                                               |
| differences | an integer representing the order of the difference.                                                                  |
| xi          | a numeric vector, matrix, or time series containing the initial values for the integrals. If missing, zeros are used. |
| ...         | arguments passed to or from other methods.                                                                            |

**Details**

`diffinv` is a generic function with methods for class `"ts"` and default for vectors and matrices.

Missing values are not handled.

**Value**

A numeric vector, matrix, or time series (the latter for the "ts" method) representing the discrete integral of  $x$ .

dist

*Distance Matrix Computation*

---

**Description**

This function computes and returns the distance matrix computed by using the specified distance measure to compute the distances between the rows of a data matrix.

**Usage**

```
dist(x, method = "euclidean", diag = FALSE, upper = FALSE, p = 2)

as.dist(m, diag = FALSE, upper = FALSE)
## Default S3 method:
as.dist(m, diag = FALSE, upper = FALSE)

## S3 method for class 'dist'
print(x, diag = NULL, upper = NULL,
      digits = getOption("digits"), justify = "none",
      right = TRUE, ...)

## S3 method for class 'dist'
as.matrix(x, ...)
```

**Arguments**

|                     |                                                                                                                                                                        |
|---------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>      | a numeric matrix, data frame or "dist" object.                                                                                                                         |
| <code>method</code> | the distance measure to be used. This must be one of "euclidean", "maximum", "manhattan", "canberra", "binary" or "minkowski". Any unambiguous substring can be given. |
| <code>diag</code>   | logical value indicating whether the diagonal of the distance matrix should be printed by <code>print.dist</code> .                                                    |

|                 |                                                                                                                                                                                                                                                                                                       |
|-----------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| upper           | logical value indicating whether the upper triangle of the distance matrix should be printed by <code>print.dist</code> .                                                                                                                                                                             |
| p               | The power of the Minkowski distance.                                                                                                                                                                                                                                                                  |
| m               | An object with distance information to be converted to a "dist" object. For the default method, a "dist" object, or a matrix (of distances) or an object which can be coerced to such a matrix using <code>as.matrix()</code> . (Only the lower triangle of the matrix is used, the rest is ignored). |
| digits, justify | passed to <code>format</code> inside of <code>print()</code> .                                                                                                                                                                                                                                        |
| right, ...      | further arguments, passed to other methods.                                                                                                                                                                                                                                                           |

## Details

Available distance measures are (written for two vectors  $x$  and  $y$ ):

**euclidean:** Usual distance between the two vectors (2 norm aka  $L_2$ ),  $\sqrt{\sum_i (x_i - y_i)^2}$ .

**maximum:** Maximum distance between two components of  $x$  and  $y$  (supremum norm)

**manhattan:** Absolute distance between the two vectors (1 norm aka  $L_1$ ).

**canberra:**  $\sum_i |x_i - y_i| / (|x_i| + |y_i|)$ . Terms with zero numerator and denominator are omitted from the sum and treated as if the values were missing.

This is intended for non-negative values (e.g., counts), in which case the denominator can be written in various equivalent ways; Originally, R used  $x_i + y_i$ , then from 1998 to 2017,  $|x_i + y_i|$ , and then the correct  $|x_i| + |y_i|$ .

**binary:** (aka *asymmetric binary*): The vectors are regarded as binary bits, so non-zero elements are 'on' and zero elements are 'off'. The distance is the *proportion* of bits in which only one is on amongst those in which at least one is on. This also called "Jaccard" distance in some contexts. Here, two all-zero observations have distance 0, whereas in traditional Jaccard definitions, the distance would be undefined for that case and give NaN numerically.

**minkowski:** The  $p$  norm, the  $p$ -th root of the sum of the  $p$ -th powers of the differences of the components.

Missing values are allowed, and are excluded from all computations involving the rows within which they occur. Further, when Inf values are involved, all pairs of values are excluded when their contribution to the distance gave NaN or NA. If some columns are excluded in calculating a Euclidean, Manhattan, Canberra or Minkowski distance, the sum is scaled up proportionally to the number of columns used. If all pairs are excluded when calculating a particular distance, the value is NA.

The "dist" method of `as.matrix()` and `as.dist()` can be used for conversion between objects of class "dist" and conventional distance matrices.

`as.dist()` is a generic function. Its default method handles objects inheriting from class "dist", or coercible to matrices using `as.matrix()`. Support for classes representing distances (also known as dissimilarities) can be added by providing an `as.matrix()` or, more directly, an `as.dist` method for such a class.

## Value

`dist` returns an object of class "dist".

The lower triangle of the distance matrix stored by columns in a vector, say `do`. If  $n$  is the number of observations, i.e.,  $n \leftarrow \text{attr}(\text{do}, "Size")$ , then for  $i < j \leq n$ , the dissimilarity between (row)  $i$  and  $j$  is `do[n*(i-1) - i*(i-1)/2 + j-i]`. The length of the vector is  $n * (n - 1) / 2$ , i.e., of order  $n^2$ .

The object has the following attributes (besides "class" equal to "dist"):

|             |                                                                                                                               |
|-------------|-------------------------------------------------------------------------------------------------------------------------------|
| Size        | integer, the number of observations in the dataset.                                                                           |
| Labels      | optionally, contains the labels, if any, of the observations of the dataset.                                                  |
| Diag, Upper | logicals corresponding to the arguments diag and upper above, specifying how the object should be printed.                    |
| call        | optionally, the <code>call</code> used to create the object.                                                                  |
| method      | optionally, the distance method used; resulting from <code>dist()</code> , the <code>(match.arg())</code> ed method argument. |

`daisy` in the `cluster` package with more possibilities in the case of *mixed* (continuous / categorical) variables. `hclust`.

## Examples

```
require(graphics)

x <- matrix(rnorm(100), nrow = 5)
dist(x)
dist(x, diag = TRUE)
dist(x, upper = TRUE)
m <- as.matrix(dist(x))
d <- as.dist(m)
stopifnot(d == dist(x))

## Use correlations between variables "as distance"
dd <- as.dist((1 - cor(USJudgeRatings))/2)
round(1000 * dd) # (prints more nicely)
plot(hclust(dd)) # to see a dendrogram of clustered variables

## example of binary and canberra distances.
x <- c(0, 0, 1, 1, 1, 1)
y <- c(1, 0, 1, 1, 0, 1)
dist(rbind(x, y), method = "binary")
## answer 0.4 = 2/5
dist(rbind(x, y), method = "canberra")
## answer 2 * (6/5)

## To find the names
labels(eurodist)

## Examples involving "Inf" :
## 1)
x[6] <- Inf
(m2 <- rbind(x, y))
dist(m2, method = "binary") # warning, answer 0.5 = 2/4
```

```
## These all give "Inf":
stopifnot(Inf == dist(m2, method = "euclidean"),
          Inf == dist(m2, method = "maximum"),
          Inf == dist(m2, method = "manhattan"))
## "Inf" is same as very large number:
x1 <- x; x1[6] <- 1e100
stopifnot(dist(cbind(x, y), method = "canberra") ==
          print(dist(cbind(x1, y), method = "canberra")))

## 2)
y[6] <- Inf #-> 6-th pair is excluded
dist(rbind(x, y), method = "binary" ) # warning; 0.5
dist(rbind(x, y), method = "canberra" ) # 3
dist(rbind(x, y), method = "maximum" ) # 1
dist(rbind(x, y), method = "manhattan" ) # 2.4
```

Distributions

Distributions in the stats package

---

## Description

Density, cumulative distribution function, quantile function and random variate generation for many standard probability distributions are available in the **stats** package.

## Details

The functions for the density/mass function, cumulative distribution function, quantile function and random variate generation are named in the form `dxxx`, `pxxx`, `qxxx` and `rxxx` respectively.

For the beta distribution see [dbeta](#).

For the binomial (including Bernoulli) distribution see [dbinom](#).

For the Cauchy distribution see [dcauchy](#).

For the chi-squared distribution see [dchisq](#).

For the exponential distribution see [dexp](#).

For the F distribution see [df](#).

For the gamma distribution see [dgamma](#).

For the geometric distribution see [dgeom](#). (This is also a special case of the negative binomial.)

For the hypergeometric distribution see [dhyper](#).

For the log-normal distribution see [dlnorm](#).

For the multinomial distribution see [dmultinom](#).

For the negative binomial distribution see [dnbinom](#).

For the normal distribution see [dnorm](#).

For the Poisson distribution see [dpois](#).

For the Student's t distribution see [dt](#).

For the uniform distribution see [dunif](#).

For the Weibull distribution see [dweibull](#).

For less common distributions of test statistics see [pbirthday](#), [dsignrank](#), [ptukey](#) and [dwilcox](#) (and see the 'See Also' section of [cor.test](#)).

**See Also**

[RNG](#) about random number generation in R.

The CRAN task view on distributions, <https://CRAN.R-project.org/view=Distributions>, mentioning several CRAN packages for additional distributions.

dummy.coef

*Extract Coefficients in Original Coding***Description**

This extracts coefficients in terms of the original levels of the coefficients rather than the coded variables.

**Usage**

```
dummy.coef(object, ...)

## S3 method for class 'lm'
dummy.coef(object, use.na = FALSE, ...)

## S3 method for class 'aovlist'
dummy.coef(object, use.na = FALSE, ...)
```

**Arguments**

|        |                                                                                                                                                             |
|--------|-------------------------------------------------------------------------------------------------------------------------------------------------------------|
| object | a linear model fit.                                                                                                                                         |
| use.na | logical flag for coefficients in a singular model. If use.na is true, undetermined coefficients will be missing; if false they will get one possible value. |
| ...    | arguments passed to or from other methods.                                                                                                                  |

**Details**

A fitted linear model has coefficients for the contrasts of the factor terms, usually one less in number than the number of levels. This function re-expresses the coefficients in the original coding; as the coefficients will have been fitted in the reduced basis, any implied constraints (e.g., zero sum for `contr.helmert` or `contr.sum`) will be respected. There will be little point in using `dummy.coef` for `contr.treatment` contrasts, as the missing coefficients are by definition zero.

The method used has some limitations, and will give incomplete results for terms such as `poly(x, 2)`. However, it is adequate for its main purpose, aov models.

**Value**

A list giving for each term the values of the coefficients. For a multistratum aov model, such a list for each stratum.

**Warning**

This function is intended for human inspection of the output: it should not be used for calculations. Use coded variables for all calculations.

The results differ from S for singular values, where S can be incorrect.

**See Also**

[aov](#), [model.tables](#)

**Examples**

```
options(contrasts = c("contr.helmert", "contr.poly"))
## From Venables and Ripley (2002) p.165.
npk.aov <- aov(yield ~ block + N*P*K, npk)
dummy.coef(npk.aov)

npk.aovE <- aov(yield ~ N*P*K + Error(block), npk)
dummy.coef(npk.aovE)
```

---

ecdf

*Empirical Cumulative Distribution Function*

---

**Description**

Compute an empirical cumulative distribution function, with several methods for plotting, printing and computing with such an “ecdf” object.

**Usage**

```
ecdf(x)

## S3 method for class 'ecdf'
plot(x, ..., ylab="Fn(x)", verticals = FALSE,
      col.01line = "gray70", pch = 19)

## S3 method for class 'ecdf'
print(x, digits= getOption("digits") - 2, ...)

## S3 method for class 'ecdf'
summary(object, ...)
## S3 method for class 'ecdf'
quantile(x, ...)
```

**Arguments**

|            |                                                                                                                |
|------------|----------------------------------------------------------------------------------------------------------------|
| x, object  | numeric vector of the observations for ecdf; for the methods, an object inheriting from class "ecdf".          |
| ...        | arguments to be passed to subsequent methods, e.g., <a href="#">plot.stepfun</a> for the plot method.          |
| ylab       | label for the y-axis.                                                                                          |
| verticals  | see <a href="#">plot.stepfun</a> .                                                                             |
| col.01line | numeric or character specifying the color of the horizontal lines at y = 0 and 1, see <a href="#">colors</a> . |
| pch        | plotting character.                                                                                            |
| digits     | number of significant digits to use, see <a href="#">print</a> .                                               |

## Details

The e.c.d.f. (empirical cumulative distribution function)  $F_n$  is a step function with jumps  $i/n$  at observation values, where  $i$  is the number of tied observations at that value. Missing values are ignored.

For observations  $x = (x_1, x_2, \dots, x_n)$ ,  $F_n$  is the fraction of observations less or equal to  $t$ , i.e.,

$$F_n(t) = \#\{x_i \leq t\} / n = \frac{1}{n} \sum_{i=1}^n \mathbf{1}_{[x_i \leq t]}.$$

The function `plot.ecdf` which implements the `plot` method for `ecdf` objects, is implemented via a call to `plot.stepfun`; see its documentation.

## Value

For `ecdf`, a function of class "ecdf", inheriting from the "stepfun" class, and hence inheriting a `knots()` method.

For the summary method, a summary of the knots of object with a "header" attribute.

The `quantile(obj, ...)` method computes the same quantiles as `quantile(x, ...)` would where `x` is the original sample.

## Note

The objects of class "ecdf" are not intended to be used for permanent storage and may change structure between versions of R (and did at R 3.0.0). They can usually be re-created by

```
eval(attr(old_obj, "call"), environment(old_obj))
```

since the data used is stored as part of the object's environment.

## Author(s)

Martin Maechler; fixes and new features by other R-core members.

## See Also

`stepfun`, the more general class of step functions, `approxfun` and `splinefun`.

## Examples

```
##-- Simple didactical ecdf example :
x <- rnorm(12)
Fn <- ecdf(x)
Fn      # a *function*
Fn(x)   # returns the percentiles for x
tt <- seq(-2, 2, by = 0.1)
12 * Fn(tt) # Fn is a 'simple' function {with values k/12}
summary(Fn)
##--> see below for graphics
knots(Fn) # the unique data values {12 of them if there were no ties}

y <- round(rnorm(12), 1); y[3] <- y[1]
Fn12 <- ecdf(y)
Fn12
```

```

knots(Fn12) # unique values (always less than 12!)
summary(Fn12)
summary.stepfun(Fn12)

## Advanced: What's inside the function closure?
ls(environment(Fn12))
## "f"      "method" "na.rm" "nobs"  "x"      "y"      "yleft"  "yright"
utils::ls.str(environment(Fn12))
stopifnot(all.equal(quantile(Fn12), quantile(y)))

###----- Plotting -----
require(graphics)

op <- par(mfrow = c(3, 1), mgp = c(1.5, 0.8, 0), mar = .1+c(3,3,2,1))

F10 <- ecdf(rnorm(10))
summary(F10)

plot(F10)
plot(F10, verticals = TRUE, do.points = FALSE)

plot(Fn12, lwd = 2) ; mtext("lwd = 2", adj = 1)
xx <- unique(sort(c(seq(-3, 2, length.out = 201), knots(Fn12))))
lines(xx, Fn12(xx), col = "blue")
abline(v = knots(Fn12), lty = 2, col = "gray70")

plot(xx, Fn12(xx), type = "o", cex = .1) #- plot.default {ugly}
plot(Fn12, col.hor = "red", add = TRUE) #- plot method
abline(v = knots(Fn12), lty = 2, col = "gray70")
## luxury plot
plot(Fn12, verticals = TRUE, col.points = "blue",
     col.hor = "red", col.vert = "bisque")

##-- this works too (automatic call to ecdf(.)):
plot.ecdf(rnorm(24))
title("via simple plot.ecdf(x)", adj = 1)

par(op)

```

---

eff.aovlist

---

*Compute Efficiencies of Multistratum Analysis of Variance*

---

## Description

Computes the efficiencies of fixed-effect terms in an analysis of variance model with multiple strata.

## Usage

```
eff.aovlist(aovlist)
```

## Arguments

aovlist            The result of a call to aov with an Error term.

effects

*Effects from Fitted Model***Description**

Returns (orthogonal) effects from a fitted model, usually a linear model. This is a generic function, but currently only has a methods for objects inheriting from classes "lm" and "glm".

**Usage**

```
effects(object, ...)

## S3 method for class 'lm'
effects(object, set.sign = FALSE, ...)
```

**Arguments**

|          |                                                                                                                                                                                              |
|----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| object   | an R object; typically, the result of a model fitting function such as <a href="#">lm</a> .                                                                                                  |
| set.sign | logical. If TRUE, the sign of the effects corresponding to coefficients in the model will be set to agree with the signs of the corresponding coefficients, otherwise the sign is arbitrary. |
| ...      | arguments passed to or from other methods.                                                                                                                                                   |

**Details**

For a linear model fitted by [lm](#) or [aov](#), the effects are the uncorrelated single-degree-of-freedom values obtained by projecting the data onto the successive orthogonal subspaces generated by the QR decomposition during the fitting process. The first  $r$  (the rank of the model) are associated with coefficients and the remainder span the space of residuals (but are not associated with particular residuals).

Empty models do not have effects.

**Value**

A (named) numeric vector of the same length as [residuals](#), or a matrix if there were multiple responses in the fitted model, in either case of class "coef".

The first  $r$  rows are labelled by the corresponding coefficients, and the remaining rows are unlabelled. Note that in rank-deficient models the corresponding coefficients will be in a different order if pivoting occurred.

**References**

Chambers, J. M. and Hastie, T. J. (1992) *Statistical Models in S*. Wadsworth & Brooks/Cole.

**See Also**

[coef](#)

**Examples**

```

y <- c(1:3, 7, 5)
x <- c(1:3, 6:7)
( ee <- effects(lm(y ~ x)) )
c( round(ee - effects(lm(y+10 ~ I(x-3.8)))), 3) )
# just the first is different

```

embed

*Embedding a Time Series***Description**

Embeds the time series  $x$  into a low-dimensional Euclidean space.

**Usage**

```
embed (x, dimension = 1)
```

**Arguments**

$x$  a numeric vector, matrix, or time series.  
 $dimension$  a scalar representing the embedding dimension.

**Details**

Each row of the resulting matrix consists of sequences  $x[t]$ ,  $x[t-1]$ , ...,  $x[t-dimension+1]$ , where  $t$  is the original index of  $x$ . If  $x$  is a matrix, i.e.,  $x$  contains more than one variable, then  $x[t]$  consists of the  $t$ -th observation on each variable.

**Value**

A matrix containing the embedded time series  $x$ .

**Author(s)**

A. Trapletti, B.D. Ripley

**Examples**

```

x <- 1:10
embed (x, 3)

```

---

|                    |                                           |
|--------------------|-------------------------------------------|
| expand.model.frame | <i>Add new variables to a model frame</i> |
|--------------------|-------------------------------------------|

---

## Description

Evaluates new variables as if they had been part of the formula of the specified model. This ensures that the same `na.action` and `subset` arguments are applied and allows, for example, `x` to be recovered for a model using `sin(x)` as a predictor.

## Usage

```
expand.model.frame(model, extras,
                   envir = environment(formula(model)),
                   na.expand = FALSE)
```

## Arguments

|                        |                                                                                       |
|------------------------|---------------------------------------------------------------------------------------|
| <code>model</code>     | a fitted model                                                                        |
| <code>extras</code>    | one-sided formula or vector of character strings describing new variables to be added |
| <code>envir</code>     | an environment to evaluate things in                                                  |
| <code>na.expand</code> | logical; see below                                                                    |

## Details

If `na.expand = FALSE` then NA values in the extra variables will be passed to the `na.action` function used in `model`. This may result in a shorter data frame (with [na.omit](#)) or an error (with [na.fail](#)). If `na.expand = TRUE` the returned data frame will have precisely the same rows as `model.frame(model)`, but the columns corresponding to the extra variables may contain NA.

## Value

A data frame.

## See Also

[model.frame](#), [predict](#)

## Examples

```
model <- lm(log(Volume) ~ log(Girth) + log(Height), data = trees)
expand.model.frame(model, ~ Girth) # prints data.frame like

dd <- data.frame(x = 1:5, y = rnorm(5), z = c(1,2,NA,4,5))
model <- glm(y ~ x, data = dd, subset = 1:4, na.action = na.omit)
expand.model.frame(model, "z", na.expand = FALSE) # = default
expand.model.frame(model, "z", na.expand = TRUE)
```

## Exponential

*The Exponential Distribution***Description**

Density, distribution function, quantile function and random generation for the exponential distribution with rate *rate* (i.e., mean  $1/\text{rate}$ ).

**Usage**

```
dexp(x, rate = 1, log = FALSE)
pexp(q, rate = 1, lower.tail = TRUE, log.p = FALSE)
qexp(p, rate = 1, lower.tail = TRUE, log.p = FALSE)
rexp(n, rate = 1)
```

**Arguments**

|                           |                                                                                                    |
|---------------------------|----------------------------------------------------------------------------------------------------|
| <i>x</i> , <i>q</i>       | vector of quantiles.                                                                               |
| <i>p</i>                  | vector of probabilities.                                                                           |
| <i>n</i>                  | number of observations. If $\text{length}(n) > 1$ , the length is taken to be the number required. |
| <i>rate</i>               | vector of rates.                                                                                   |
| <i>log</i> , <i>log.p</i> | logical; if TRUE, probabilities <i>p</i> are given as $\log(p)$ .                                  |
| <i>lower.tail</i>         | logical; if TRUE (default), probabilities are $P[X \leq x]$ , otherwise, $P[X > x]$ .              |

**Details**

If *rate* is not specified, it assumes the default value of 1.

The exponential distribution with rate  $\lambda$  has density

$$f(x) = \lambda e^{-\lambda x}$$

for  $x \geq 0$ .

**Value**

*dexp* gives the density, *pexp* gives the distribution function, *qexp* gives the quantile function, and *rexp* generates random deviates.

The length of the result is determined by *n* for *rexp*, and is the maximum of the lengths of the numerical arguments for the other functions.

The numerical arguments other than *n* are recycled to the length of the result. Only the first elements of the logical arguments are used.

**Note**

The cumulative hazard  $H(t) = -\log(1 - F(t))$  is `-pexp(t, r, lower = FALSE, log = TRUE)`.

## Source

dexp, pexp and qexp are all calculated from numerically stable versions of the definitions.

rexp uses

extractAIC

*Extract AIC from a Fitted Model*

---

## Description

Computes the (generalized) Akaike An Information Criterion for a fitted parametric model.

## Usage

```
extractAIC(fit, scale, k = 2, ...)
```

## Arguments

|       |                                                                                                                                                                                                                                                                                               |
|-------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| fit   | fitted model, usually the result of a fitter like <a href="#">lm</a> .                                                                                                                                                                                                                        |
| scale | optional numeric specifying the scale parameter of the model, see <a href="#">scale</a> in <a href="#">step</a> . Currently only used in the "lm" method, where scale specifies the estimate of the error variance, and scale = 0 indicates that it is to be estimated by maximum likelihood. |
| k     | numeric specifying the ‘weight’ of the <i>equivalent degrees of freedom</i> ( $\equiv$ edf) part in the AIC formula.                                                                                                                                                                          |
| ...   | further arguments (currently unused in base R).                                                                                                                                                                                                                                               |

## Details

This is a generic function, with methods in base R for classes "aov", "glm" and "lm" as well as for "negbin" (package **MASS**) and "coxph" and "survreg" (package **survival**).

The criterion used is

$$AIC = -2 \log L + k \times \text{edf},$$

where  $L$  is the likelihood and edf the equivalent degrees of freedom (i.e., the number of free parameters for usual parametric models) of fit.

For linear models with unknown scale (i.e., for **lm** and **aov**),  $-2 \log L$  is computed from the *deviance* and uses a different additive constant to **logLik** and hence **AIC**. If  $RSS$  denotes the (weighted) residual sum of squares then **extractAIC** uses for  $-2 \log L$  the formulae  $RSS/s - n$  (corresponding to Mallows'  $C_p$ ) in the case of known scale  $s$  and  $n \log(RSS/n)$  for unknown scale. **AIC** only handles unknown scale and uses the formula  $n \log(RSS/n) + n + n \log 2\pi - \sum \log w$  where  $w$  are the weights. Further **AIC** counts the scale estimation as a parameter in the edf and **extractAIC** does not.

For **glm** fits the family's **aic()** function is used to compute the **AIC**: see the note under **logLik** about the assumptions this makes.

$k = 2$  corresponds to the traditional **AIC**, using  $k = \log(n)$  provides the **BIC** (Bayesian IC) instead.

Note that the methods for this function may differ in their assumptions from those of methods for **AIC** (usually *via* a method for **logLik**). We have already mentioned the case of "lm" models with estimated scale, and there are similar issues in the "glm" and "negbin" methods where the dispersion parameter may or may not be taken as 'free'. This is immaterial as **extractAIC** is only used to compare models of the same class (where only differences in **AIC** values are considered).

## Value

A numeric vector of length 2, with first and second elements giving

|     |                                                                               |
|-----|-------------------------------------------------------------------------------|
| edf | the 'equivalent <b>d</b> egrees of <b>f</b> reedom' for the fitted model fit. |
| AIC | the (generalized) Akaike Information Criterion for fit.                       |

## Note

This function is used in **add1**, **drop1** and **step** and the similar functions in package **MASS** from which it was adopted.

extractAIC(glm.D93) #>> 5 15.129
```

## factanal

*Factor Analysis***Description**

Perform maximum-likelihood factor analysis on a covariance matrix or data matrix.

**Usage**

```
factanal(x, factors, data = NULL, covmat = NULL, n.obs = NA,
        subset, na.action, start = NULL,
        scores = c("none", "regression", "Bartlett"),
        rotation = "varimax", control = NULL, ...)
```

**Arguments**

|           |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|-----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| x         | <a href="#">formula</a> or a numeric matrix or an object that can be coerced to a numeric matrix.                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| factors   | integer number of factors to be fitted.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| data      | an optional data frame (or similar: see <a href="#">model.frame</a> ), used only if x is a formula. By default the variables are taken from <code>environment(formula)</code> .                                                                                                                                                                                                                                                                                                                                                            |
| covmat    | covariance matrix or a covariance list as returned by <a href="#">cov.wt</a> . Of course, correlation matrices are covariance matrices.                                                                                                                                                                                                                                                                                                                                                                                                    |
| n.obs     | the number of observations, used if covmat is a covariance matrix.                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| subset    | a specification of the cases to be used, if x is used as a matrix or formula.                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| na.action | the <a href="#">na.action</a> to be used if x is used as a formula, in which case <a href="#">model.frame()</a> is called.                                                                                                                                                                                                                                                                                                                                                                                                                 |
| start     | NULL or a matrix of starting values, each column giving an initial set of uniquenesses.                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| scores    | Type of scores to produce, if any. The default is none, "regression" gives Thompson's scores, "Bartlett" given Bartlett's weighted least-squares scores. Partial matching allows these names to be abbreviated.                                                                                                                                                                                                                                                                                                                            |
| rotation  | a <a href="#">function</a> or <a href="#">character</a> string. In the latter case, "none" or the name of a function to be used to rotate the factors: it will be called with first argument the loadings matrix, and should return a list with component loadings giving the rotated loadings, or just the rotated loadings.                                                                                                                                                                                                              |
| control   | a <a href="#">list</a> of control values with components <ul style="list-style-type: none"> <li>nstart The number of starting values to be tried if start = NULL. Default 1.</li> <li>trace logical. Output tracing information? Default FALSE.</li> <li>lower The lower bound for uniquenesses during optimization. Should be &gt; 0. Default 0.005.</li> <li>opt a list of control values to be passed to <a href="#">optim</a>'s control argument.</li> <li>rotate a list of additional arguments for the rotation function.</li> </ul> |
| ...       | components of control can also be supplied directly as named arguments to factanal.                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

## Details

The factor analysis model is

$$x = \Lambda f + e$$

for a  $p$ -element vector  $x$ , a  $p \times k$  matrix  $\Lambda$  of *loadings*, a  $k$ -element vector  $f$  of *scores* and a  $p$ -element vector  $e$  of errors. None of the components other than  $x$  is observed, but the major restriction is that the scores be uncorrelated and of unit variance, and that the errors be independent with variances  $\Psi$ , the *uniquenesses*. It is also common to scale the observed variables to unit variance, and done in this function.

Thus factor analysis is in essence a model for the correlation matrix of  $x$ ,

$$\Sigma = \Lambda\Lambda' + \Psi$$

There is still some indeterminacy in the model for it is unchanged if  $\Lambda$  is replaced by  $G\Lambda$  for any orthogonal matrix  $G$ . Such matrices  $G$  are known as *rotations* (although the term is applied also to non-orthogonal invertible matrices).

If `covmat` is supplied it is used. Otherwise `x` is used if it is a matrix, or a formula `x` is used with data to construct a model matrix, and that is used to construct a covariance matrix. (It makes no sense for the formula to have a response, and all the variables must be numeric.) Once a covariance matrix is found or calculated from `x`, it is converted to a correlation matrix for analysis. The correlation matrix is returned as component `correlation` of the result.

The fit is done by optimizing the log likelihood assuming multivariate normality over the uniquenesses. (The maximizing loadings for given uniquenesses can be found analytically: Lawley & Maxwell (1971, p. 27).) All the starting values supplied in `start` are tried in turn and the best fit obtained is used. If `start = NULL` then the first fit is started at the value suggested by Jöreskog (1963) and given by Lawley & Maxwell (1971, p. 31), and then `control$start - 1` other values are tried, randomly selected as equal values of the uniquenesses.

The uniquenesses are technically constrained to lie in  $[0, 1]$ , but near-zero values are problematical, and the optimization is done with a lower bound of `control$lower`, default 0.005 (Lawley & Maxwell, 1971, p. 32).

Scores can only be produced if a data matrix is supplied and used. The first method is the regression method of Thomson (1951), the second the weighted least squares method of Bartlett (1937, 8). Both are estimates of the unobserved scores  $f$ . Thomson's method regresses (in the population) the unknown  $f$  on  $x$  to yield

$$\hat{f} = \Lambda' \Sigma^{-1} x$$

and then substitutes the sample estimates of the quantities on the right-hand side. Bartlett's method minimizes the sum of squares of standardized errors over the choice of  $f$ , given (the fitted)  $\Lambda$ .

If `x` is a formula then the standard NA-handling is applied to the scores (if requested): see [napredict](#).

The `print` method (documented under [loadings](#)) follows the factor analysis convention of drawing attention to the patterns of the results, so the default precision is three decimal places, and small loadings are suppressed.

## Value

An object of class "factanal" with components

|          |                                                                                                                                                                                                                                                                                                                                                                                  |
|----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| loadings | A matrix of loadings, one column for each factor. The factors are ordered in decreasing order of sums of squares of loadings, and given the sign that will make the sum of the loadings positive. For correlated factors, the correlation matrix is stored as an attribute labeled "covariance". This is of class "loadings": see <a href="#">loadings</a> for its print method. |
|----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

|                 |                                                                                                                                                        |
|-----------------|--------------------------------------------------------------------------------------------------------------------------------------------------------|
| uniquenesses    | The uniquenesses computed.                                                                                                                             |
| correlation     | The correlation matrix used.                                                                                                                           |
| criteria        | The results of the optimization: the value of the criterion (a linear function of the negative log-likelihood) and information on the iterations used. |
| factors         | The argument factors.                                                                                                                                  |
| dof             | The number of degrees of freedom of the factor analysis model.                                                                                         |
| method          | The method: always "mle".                                                                                                                              |
| rotmat          | The rotation matrix if relevant.                                                                                                                       |
| scores          | If requested, a matrix of scores. <code>napredict</code> is applied to handle the treatment of values omitted by the <code>na.action</code> .          |
| n.obs           | The number of observations if available, or NA.                                                                                                        |
| call            | The matched call.                                                                                                                                      |
| na.action       | If relevant.                                                                                                                                           |
| STATISTIC, PVAL | The significance-test statistic and P value, if it can be computed.                                                                                    |

### Note

There are so many variations on factor analysis that it is hard to compare output from different programs. Further, the optimization in maximum likelihood factor analysis is hard, and many other examples we compared had less good fits than produced by this function. In particular, solutions which are ‘Heywood cases’ (with one or more uniquenesses essentially zero) are much more common than most texts and some other programs would lead one to believe.

|              |                                                                        |
|--------------|------------------------------------------------------------------------|
| factor.scope | <i>Compute Allowed Changes in Adding to or Dropping from a Formula</i> |
|--------------|------------------------------------------------------------------------|

---

## Description

add.scope and drop.scope compute those terms that can be individually added to or dropped from a model while respecting the hierarchy of terms.

## Usage

```

add.scope(terms1, terms2)

drop.scope(terms1, terms2)

factor.scope(factor, scope)

```

## Arguments

|        |                                                                                                                                                                                                             |
|--------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| terms1 | the terms or formula for the base model.                                                                                                                                                                    |
| terms2 | the terms or formula for the upper (add.scope) or lower (drop.scope) scope. If missing for drop.scope it is taken to be the null formula, so all terms (except any intercept) are candidates to be dropped. |
| factor | the "factor" attribute of the terms of the base object.                                                                                                                                                     |
| scope  | a list with one or both components drop and add giving the "factor" attribute of the lower and upper scopes respectively.                                                                                   |

## Details

factor.scope is not intended to be called directly by users.

## Value

For add.scope and drop.scope a character vector of terms labels. For factor.scope, a list with components drop and add, character vectors of terms labels.

**See Also**

[add1](#), [drop1](#), [aov](#), [lm](#)

**Examples**

```
add.scope( ~ a + b + c + a:b, ~ (a + b + c)^3)
# [1] "a:c" "b:c"
drop.scope( ~ a + b + c + a:b)
# [1] "c"   "a:b"
```

family

*Family Objects for Models*

---

**Description**

Family objects provide a convenient way to specify the details of the models used by functions such as [glm](#). See the documentation for [glm](#) for the details on how such model fitting takes place.

**Usage**

```
family(object, ...)

binomial(link = "logit")
gaussian(link = "identity")
Gamma(link = "inverse")
inverse.gaussian(link = "1/mu^2")
poisson(link = "log")
quasi(link = "identity", variance = "constant")
quasibinomial(link = "logit")
quasipoisson(link = "log")
```

**Arguments**

|          |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

## Details

family is a generic function with methods for classes "glm" and "lm" (the latter returning gaussian()).

For the binomial and quasibinomial families the response can be specified in one of three ways:

1. As a factor: 'success' is interpreted as the factor not having the first level (and hence usually of having the second level).
2. As a numerical vector with values between 0 and 1, interpreted as the proportion of successful cases (with the total number of cases given by the weights).
3. As a two-column integer matrix: the first column gives the number of successes and the second the number of failures.

The quasibinomial and quasipoisson families differ from the binomial and poisson families only in that the dispersion parameter is not fixed at one, so they can model over-dispersion. For the binomial case see McCullagh and Nelder (1989, pp. 124–8). Although they show that there is (under some restrictions) a model with variance proportional to mean as in the quasi-binomial model, note that glm does not compute maximum-likelihood estimates in that model. The behaviour of S is closer to the quasi- variants.

## Value

An object of class "family" (which has a concise print method). This is a list with elements

|            |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| family     | character: the family name.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| link       | character: the link name.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| linkfun    | function: the link.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| linkinv    | function: the inverse of the link function.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| variance   | function: the variance as a function of the mean.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| dev.resids | function giving the deviance for each observation as a function of (y, mu, wt), used by the <a href="#">residuals</a> method when computing deviance residuals.                                                                                                                                                                                                                                                                                                                                                                                    |
| aic        | function giving the AIC value if appropriate (but NA for the quasi- families). More precisely, this function returns $-2\ell + 2s$ , where $\ell$ is the log-likelihood and $s$ is the number of estimated scale parameters. Note that the penalty term for the location parameters (typically the "regression coefficients") is added elsewhere, e.g., in <a href="#">glm.fit()</a> , or <a href="#">AIC()</a> , see the AIC example in <a href="#">glm</a> . See <a href="#">logLik</a> for the assumptions made about the dispersion parameter. |
| mu.eta     | function: derivative of the inverse-link function with respect to the linear predictor. If the inverse-link function is $\mu = g^{-1}(\eta)$ where $\eta$ is the value of the linear predictor, then this function returns $d(g^{-1})/d\eta = d\mu/d\eta$ .                                                                                                                                                                                                                                                                                        |
| initialize | expression. This needs to set up whatever data objects are needed for the family as well as n (needed for AIC in the binomial family) and mustart (see <a href="#">glm</a> ).                                                                                                                                                                                                                                                                                                                                                                      |
| validmu    | logical function. Returns TRUE if a mean vector mu is within the domain of variance.                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| valideta   | logical function. Returns TRUE if a linear predictor eta is within the domain of linkinv.                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

|            |                                                                                                                                                                                                                                                                                                                                          |
|------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| simulate   | (optional) function <code>simulate(object, nsim)</code> to be called by the "lm" method of <a href="#">simulate</a> . It will normally return a matrix with <code>nsim</code> columns and one row for each fitted value, but it can also return a list of length <code>nsim</code> . Clearly this will be missing for 'quasi-' families. |
| dispersion | (optional since R version 4.3.0) numeric: value of the dispersion parameter, if fixed, or <code>NA_real_</code> if free.                                                                                                                                                                                                                 |

### Note

The `link` and `variance` arguments have rather awkward semantics for back-compatibility. The recommended way is to supply them as quoted character strings, but they can also be supplied unquoted (as names or expressions). Additionally, they can be supplied as a length-one character vector giving the name of one of the options, or as a list (for `link`, of class "link-glm"). The restrictions apply only to links given as names: when given as a character string all the links known to [make.link](#) are accepted.

This is potentially ambiguous: supplying `link = logit` could mean the unquoted name of a link or the value of object `logit`. It is interpreted if possible as the name of an allowed link, then as an object. (You can force the interpretation to always be the value of an object via `logit[1]`.)

### Author(s)

The design was inspired by S functions of the same names described in Hastie & Pregibon (1992) (except `quasibinomial` and `quasipoisson`).

### Examples

```
require(utils) # for str

nf <- gaussian() # Normal family
nf
str(nf)

gf <- Gamma()
gf
str(gf)
gf$linkinv
gf$variance(-3:4) #- == (.)^2
```

```

## Binomial with default 'logit' link: Check some properties visually:
bi <- binomial()
et <- seq(-10,10, by=1/8)
plot(et, bi$mu.eta(et), type="l")
## show that mu.eta() is derivative of linkinv() :
lines((et[-1]+et[-length(et)])/2, col=adjustcolor("red", 1/4),
      diff(bi$linkinv(et))/diff(et), type="l", lwd=4)
## which here is the logistic density:
lines(et, dlogis(et), lwd=3, col=adjustcolor("blue", 1/4))
stopifnot(exprs = {
  all.equal(bi$mu.eta(et), dlogis(et))
  all.equal(bi$linkinv(et), plogis(et) -> m)
  all.equal(bi$linkfun(m), qlogis(m)) # logit(.) == qlogis(.) !
})

## Data from example(glm) :
d.AD <- data.frame(treatment = gl(3,3),
                   outcome   = gl(3,1,9),
                   counts    = c(18,17,15, 20,10,20, 25,13,12))
glm.D93 <- glm(counts ~ outcome + treatment, d.AD, family = poisson())
## Quasipoisson: compare with above / example(glm) :
glm.qD93 <- glm(counts ~ outcome + treatment, d.AD, family = quasipoisson())

glm.qD93
anova (glm.qD93, test = "F")
summary(glm.qD93)
## for Poisson results (same as from 'glm.D93' !) use
anova (glm.qD93, dispersion = 1, test = "Chisq")
summary(glm.qD93, dispersion = 1)

## Example of user-specified link, a logit model for p^days
## See Shaffer, T. 2004. Auk 121(2): 526-540.
logexp <- function(days = 1)
{
  linkfun <- function(mu) qlogis(mu^(1/days))
  linkinv <- function(eta) plogis(eta)^days
  mu.eta <- function(eta) days * plogis(eta)^(days-1) *
    binomial()$mu.eta(eta)
  valideta <- function(eta) TRUE
  link <- paste0("logexp(", days, ")")
  structure(list(linkfun = linkfun, linkinv = linkinv,
                 mu.eta = mu.eta, valideta = valideta, name = link),
            class = "link-glm")
}
(bil3 <- binomial(logexp(3)))

## in practice this would be used with a vector of 'days', in
## which case use an offset of 0 in the corresponding formula
## to get the null deviance right.

## Binomial with identity link: often not a good idea, as both
## computationally and conceptually difficult:
binomial(link = "identity") ## is exactly the same as
binomial(link = make.link("identity"))

```

```
## tests of quasi
x <- rnorm(100)
y <- rpois(100, exp(1+x))
glm(y ~ x, family = quasi(variance = "mu", link = "log"))
# which is the same as
glm(y ~ x, family = poisson)
glm(y ~ x, family = quasi(variance = "mu^2", link = "log"))
## Not run: glm(y ~ x, family = quasi(variance = "mu^3", link = "log")) # fails
y <- rbinom(100, 1, plogis(x))
# need to set a starting value for the next fit
glm(y ~ x, family = quasi(variance = "mu(1-mu)", link = "logit"), start = c(0,1))
```

FDist

*The F Distribution***Description**

Density, distribution function, quantile function and random generation for the F distribution with df1 and df2 degrees of freedom (and optional non-centrality parameter ncp).

**Usage**

```
df(x, df1, df2, ncp, log = FALSE)
pf(q, df1, df2, ncp, lower.tail = TRUE, log.p = FALSE)
qf(p, df1, df2, ncp, lower.tail = TRUE, log.p = FALSE)
rf(n, df1, df2, ncp)
```

**Arguments**

|            |                                                                                          |
|------------|------------------------------------------------------------------------------------------|
| x, q       | vector of quantiles.                                                                     |
| p          | vector of probabilities.                                                                 |
| n          | number of observations. If length(n) > 1, the length is taken to be the number required. |
| df1, df2   | degrees of freedom. Inf is allowed.                                                      |
| ncp        | non-centrality parameter. If omitted the central F is assumed.                           |
| log, log.p | logical; if TRUE, probabilities p are given as log(p).                                   |
| lower.tail | logical; if TRUE (default), probabilities are $P[X \leq x]$ , otherwise, $P[X > x]$ .    |

**Details**

The F distribution with  $df1 = \nu_1$  and  $df2 = \nu_2$  degrees of freedom has density

$$f(x) = \frac{\Gamma(\nu_1/2 + \nu_2/2)}{\Gamma(\nu_1/2)\Gamma(\nu_2/2)} \left(\frac{\nu_1}{\nu_2}\right)^{\nu_1/2} x^{\nu_1/2-1} \left(1 + \frac{\nu_1 x}{\nu_2}\right)^{-(\nu_1+\nu_2)/2}$$

for  $x > 0$ .

The F distribution's cumulative distribution function (cdf),  $F_{\nu_1, \nu_2}$  fulfills (Abramowitz & Stegun 26.6.2, p.946)  $F_{\nu_1, \nu_2}(qF) = 1 - I_x(\nu_2/2, \nu_1/2) = I_{1-x}(\nu_1/2, \nu_2/2)$ , where  $x := \frac{\nu_2}{\nu_2 + \nu_1 * qF}$ , and  $I_x(a, b)$  is the incomplete beta function; in R, = [pbeta](#)(x, a, b).

It is the distribution of the ratio of the mean squares of  $\nu_1$  and  $\nu_2$  independent standard normals, and hence of the ratio of two independent chi-squared variates each divided by its degrees of freedom. Since the ratio of a normal and the root mean-square of  $m$  independent normals has a Student's  $t_m$  distribution, the square of a  $t_m$  variate has a F distribution on 1 and  $m$  degrees of freedom.

The non-central F distribution is again the ratio of mean squares of independent normals of unit variance, but those in the numerator are allowed to have non-zero means and ncp is the sum of squares of the means. See [Chisquare](#) for further details on non-central distributions.

### Value

df gives the density, pf gives the distribution function qf gives the quantile function, and rf generates random deviates.

Invalid arguments will result in return value NaN, with a warning.

The length of the result is determined by n for rf, and is the maximum of the lengths of the numerical arguments for the other functions.

The numerical arguments other than n are recycled to the length of the result. Only the first elements of the logical arguments are used.

### Note

Supplying ncp = 0 uses the algorithm for the non-central distribution, which is not the same algorithm used if ncp is omitted. This is to give consistent behaviour in extreme cases with values of ncp very near zero.

The code for non-zero ncp is principally intended to be used for moderate values of ncp: it will not be highly accurate, especially in the tails, for large values.

### Source

For the central case of df, computed *via* a binomial probability, code contributed by Catherine Loader (see [dbinom](#)); for the non-central case computed *via* [dbeta](#), code contributed by Peter Ruckdeschel.

For pf, *via* [pbeta](#) (or for large df2, *via* [pchisq](#)).

For qf, *via* [qchisq](#) for large df2, else *via* [qbeta](#).

## Examples

```
## Equivalence of pt(.,nu) with pf(.^2, 1,nu):
x <- seq(0.001, 5, length.out = 100)
nu <- 4
stopifnot(all.equal(2*pt(x,nu) - 1, pf(x^2, 1,nu)),
  ## upper tails:
  all.equal(2*pt(x,      nu, lower.tail=FALSE),
    pf(x^2, 1,nu, lower.tail=FALSE)))

## the density of the square of a t_m is 2*dt(x, m)/(2*x)
# check this is the same as the density of F_{1,m}
all.equal(df(x^2, 1, 5), dt(x, 5)/x)

## Identity (F <-> t): qf(2*p - 1, 1, df) == qt(p, df)^2 for p >= 1/2
p <- seq(1/2, .99, length.out = 50); df <- 10
rel.err <- function(x, y) ifelse(x == y, 0, abs(x-y)/mean(abs(c(x,y))))
stopifnot(all.equal(qf(2*p - 1, df1 = 1, df2 = df),
  qt(p, df)^2))

## Identity (F <-> Beta <-> incompl.beta):
n1 <- 7 ; n2 <- 12; qF <- c((0:4)/4, 1.5, 2:16)
x <- n2/(n2 + n1*qF)
stopifnot(all.equal(pf(qF, n1, n2, lower.tail=FALSE),
  pbeta(x, n2/2, n1/2)))
```

fft

Fast Discrete Fourier Transform (FFT)

## Description

Computes the Discrete Fourier Transform (DFT) of an array with a fast algorithm, the “Fast Fourier Transform” (FFT).

## Usage

```
fft(z, inverse = FALSE)
mvfft(z, inverse = FALSE)
```

## Arguments

|                      |                                                                                                                                                                    |
|----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>z</code>       | a real or complex array containing the values to be transformed. Long vectors are not supported.                                                                   |
| <code>inverse</code> | if TRUE, the unnormalized inverse transform is computed (the inverse has a + in the exponent of $e$ , but here, we do <i>not</i> divide by $1/\text{length}(x)$ ). |

## Value

When `z` is a vector, the value computed and returned by `fft` is the unnormalized univariate discrete Fourier transform of the sequence of values in `z`. Specifically, `y <- fft(z)` returns

$$y[h] = \sum_{k=1}^n z[k] \exp(-2\pi i(k-1)(h-1)/n)$$

for  $h = 1, \dots, n$  where  $n = \text{length}(y)$ . If `inverse` is `TRUE`,  $\exp(-2\pi \dots)$  is replaced with  $\exp(2\pi \dots)$ .

When `z` contains an array, `fft` computes and returns the multivariate (spatial) transform. If `inverse` is `TRUE`, the (unnormalized) inverse Fourier transform is returned, i.e., if `y <- fft(z)`, then `z` is `fft(y, inverse = TRUE) / length(y)`.

By contrast, `mvfft` takes a real or complex matrix as argument, and returns a similar shaped matrix, but with each column replaced by its discrete Fourier transform. This is useful for analyzing vector-valued series.

The FFT is fastest when the length of the series being transformed is highly composite (i.e., has many factors). If this is not the case, the transform may take a long time to compute and will use a large amount of memory.

fft(x)
fft(fft(x), inverse = TRUE)/length(x)

## Slow Discrete Fourier Transform (DFT) - e.g., for checking the formula
fft0 <- function(z, inverse=FALSE) {
  n <- length(z)
  if(n == 0) return(z)
  k <- 0:(n-1)
  ff <- (if(inverse) 1 else -1) * 2*pi * 1i * k/n
  vapply(1:n, function(h) sum(z * exp(ff*(h-1))), complex(1))
}

relD <- function(x,y) 2* abs(x - y) / abs(x + y)
n <- 2^8
z <- complex(n, rnorm(n), rnorm(n))
## relative differences in the order of 4*10^{-14} :
summary(relD(fft(z), fft0(z)))
summary(relD(fft(z, inverse=TRUE), fft0(z, inverse=TRUE)))
```

filter

*Linear Filtering on a Time Series***Description**

Applies linear filtering to a univariate time series or to each series separately of a multivariate time series.

**Usage**

```
filter(x, filter, method = c("convolution", "recursive"),
      sides = 2, circular = FALSE, init)
```

**Arguments**

|                       |                                                                                                                                                                                                                                                                                                 |
|-----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>        | a univariate or multivariate time series.                                                                                                                                                                                                                                                       |
| <code>filter</code>   | a vector of filter coefficients in reverse time order (as for AR or MA coefficients).                                                                                                                                                                                                           |
| <code>method</code>   | Either "convolution" or "recursive" (and can be abbreviated). If "convolution" a moving average is used: if "recursive" an autoregression is used.                                                                                                                                              |
| <code>sides</code>    | for convolution filters only. If <code>sides = 1</code> the filter coefficients are for past values only; if <code>sides = 2</code> they are centred around lag 0. In this case the length of the filter should be odd, but if it is even, more of the filter is forward in time than backward. |
| <code>circular</code> | for convolution filters only. If TRUE, wrap the filter around the ends of the series, otherwise assume external values are missing (NA).                                                                                                                                                        |
| <code>init</code>     | for recursive filters only. Specifies the initial values of the time series just prior to the start value, in reverse time order. The default is a set of zeros.                                                                                                                                |

**Details**

Missing values are allowed in `x` but not in `filter` (where they would lead to missing values everywhere in the output).

Note that there is an implied coefficient 1 at lag 0 in the recursive filter, which gives

$$y_i = x_i + f_1 y_{i-1} + \cdots + f_p y_{i-p}$$

No check is made to see if recursive filter is invertible: the output may diverge if it is not.

The convolution filter is

$$y_i = f_1 x_{i+o} + \cdots + f_p x_{i+o-(p-1)}$$

where `o` is the offset: see `sides` for how it is determined.

**Value**

A time series object.

**Note**

`convolve`(, type = "filter") uses the FFT for computations and so *may* be faster for long filters on univariate series, but it does not return a time series (and so the time alignment is unclear), nor does it handle missing values. `filter` is faster for a filter of length 100 on a series of length 1000, for example.

**See Also**

`convolve`, `arima.sim`

**Examples**

```
x <- 1:100
filter(x, rep(1, 3))
filter(x, rep(1, 3), sides = 1)
filter(x, rep(1, 3), sides = 1, circular = TRUE)

filter(presidents, rep(1, 3))
```

---

fisher.test

---

*Fisher's Exact Test for Count Data*

---

**Description**

Performs Fisher's exact test for testing the null of independence of rows and columns in a contingency table with fixed marginals.

**Usage**

```
fisher.test(x, y = NULL, workspace = 200000, hybrid = FALSE,
            hybridPars = c(expect = 5, percent = 80, Emin = 1),
            control = list(), or = 1, alternative = "two.sided",
            conf.int = TRUE, conf.level = 0.95,
            simulate.p.value = FALSE, B = 2000)
```

**Arguments**

|                         |                                                                                                                                                                                                                                                                                                                                                                        |
|-------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>          | either a two-dimensional contingency table in matrix form, or a factor object.                                                                                                                                                                                                                                                                                         |
| <code>y</code>          | a factor object; ignored if <code>x</code> is a matrix.                                                                                                                                                                                                                                                                                                                |
| <code>workspace</code>  | an integer specifying the size of the workspace used in the network algorithm. In units of 4 bytes. Only used for non-simulated p-values larger than $2 \times 2$ tables. This also increases the internal stack size which allows larger problems to be solved, sometimes needing hours. In such cases, <code>simulate.p.values = TRUE</code> may be more reasonable. |
| <code>hybrid</code>     | a logical. Only used for larger than $2 \times 2$ tables, in which cases it indicates whether the exact probabilities (default) or a hybrid approximation thereof should be computed.                                                                                                                                                                                  |
| <code>hybridPars</code> | a numeric vector of length 3, by default describing "Cochran's conditions" for the validity of the chi-squared approximation, see 'Details'.                                                                                                                                                                                                                           |

|                               |                                                                                                                                                                                                                                                                                                                                      |
|-------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>control</code>          | a list with named components for low-level algorithm control. At present the only one used is "mult", a positive integer $\geq 2$ with default 30 used only for larger than $2 \times 2$ tables. This says how many times as much space should be allocated to paths as to keys: see file 'fexact.c' in the sources of this package. |
| <code>or</code>               | the hypothesized odds ratio. Only used in the $2 \times 2$ case.                                                                                                                                                                                                                                                                     |
| <code>alternative</code>      | indicates the alternative hypothesis and must be one of "two.sided", "greater" or "less". You can specify just the initial letter. Only used in the $2 \times 2$ case.                                                                                                                                                               |
| <code>conf.int</code>         | logical indicating if a confidence interval for the odds ratio in a $2 \times 2$ table should be computed (and returned).                                                                                                                                                                                                            |
| <code>conf.level</code>       | confidence level for the returned confidence interval. Only used in the $2 \times 2$ case and if <code>conf.int = TRUE</code> .                                                                                                                                                                                                      |
| <code>simulate.p.value</code> | a logical indicating whether to compute p-values by Monte Carlo simulation, in larger than $2 \times 2$ tables.                                                                                                                                                                                                                      |
| <code>B</code>                | an integer specifying the number of replicates used in the Monte Carlo test when <code>simulate.p.value</code> is true.                                                                                                                                                                                                              |

## Details

If `x` is a matrix, it is taken as a two-dimensional contingency table, and hence its entries should be nonnegative integers. Otherwise, both `x` and `y` must be vectors or factors of the same length. Incomplete cases are removed, vectors are coerced into factor objects, and the contingency table is computed from these.

For  $2 \times 2$  tables, p-values are obtained directly using the (central or non-central) hypergeometric distribution. Otherwise, computations are based on a C version of the FORTRAN subroutine FEXACT which implements the network developed by Mehta and Patel (1983, 1986) and improved by Clarkson, Fan and Joe (1993). The FORTRAN code can be obtained from <https://netlib.org/toms/643>. Note this fails (with an error message) when the entries of the table are too large. (It transposes the table if necessary so it has no more rows than columns. One constraint is that the product of the row marginals be less than  $2^{31} - 1$ .)

For  $2 \times 2$  tables, the null of conditional independence is equivalent to the hypothesis that the odds ratio equals one. 'Exact' inference can be based on observing that in general, given all marginal totals fixed, the first element of the contingency table has a non-central hypergeometric distribution with non-centrality parameter given by the odds ratio (Fisher, 1935). The alternative for a one-sided test is based on the odds ratio, so `alternative = "greater"` is a test of the odds ratio being bigger than or. Two-sided tests are based on the probabilities of the tables, and take as 'more extreme' all tables with probabilities less than or equal to that of the observed table, the p-value being the sum of such probabilities.

For larger than  $2 \times 2$  tables and `hybrid = TRUE`, asymptotic chi-squared probabilities are only used if the 'Cochran conditions' (or modified version thereof) specified by `hybridPars = c(expect = 5, percent = 80, Emin = 1)` are satisfied, that is if no cell has expected counts less than 1 (= `Emin`) and more than 80% (= `percent`) of the cells have expected counts at least 5 (= `expect`), otherwise the exact calculation is used. A corresponding `if()` decision is made for all sub-tables considered.

In the  $r \times c$  case with  $r > 2$  or  $c > 2$ , internal tables can be too large for the exact test in which case an error is signalled. Apart from increasing workspace sufficiently, which then may lead to very long running times, using `simulate.p.value = TRUE` may then often be sufficient and hence advisable.

Simulation is done conditional on the row and column marginals, and works only if the marginals are strictly positive. (A C translation of the algorithm of Patefield (1981) is used.) Note that the default number of replicates (`B = 2000`) implies a minimum p-value of about  $0.0005 (1/(B + 1))$ .

**Value**

A list with class "htest" containing the following components:

|             |                                                                                                                                                                                                             |
|-------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| p.value     | the p-value of the test.                                                                                                                                                                                    |
| conf.int    | a confidence interval for the odds ratio. Only present in the $2 \times 2$ case and if argument <code>conf.int = TRUE</code> .                                                                              |
| estimate    | an estimate of the odds ratio. Note that the <i>conditional</i> Maximum Likelihood Estimate (MLE) rather than the unconditional MLE (the sample odds ratio) is used. Only present in the $2 \times 2$ case. |
| null.value  | the odds ratio under the null, or. Only present in the $2 \times 2$ case.                                                                                                                                   |
| alternative | a character string describing the alternative hypothesis.                                                                                                                                                   |
| method      | the character string "Fisher's Exact Test for Count Data".                                                                                                                                                  |
| data.name   | a character string giving the name(s) of the data.                                                                                                                                                          |

                        list(c("Dizygotic", "Monozygotic"),
                             c("Convicted", "Not convicted")))
Convictions
fisher.test(Convictions, alternative = "less")
fisher.test(Convictions, conf.int = FALSE)
fisher.test(Convictions, conf.level = 0.95)$conf.int
fisher.test(Convictions, conf.level = 0.99)$conf.int

## A r x c table Agresti (2002, p. 57) Job Satisfaction
Job <- matrix(c(1,2,1,0, 3,3,6,1, 10,10,14,9, 6,7,12,11), 4, 4,
              dimnames = list(income = c("< 15k", "15-25k", "25-40k", "> 40k"),
                              satisfaction = c("VeryD", "LittleD", "ModerateS", "VeryS")))
fisher.test(Job) # 0.7827
fisher.test(Job, simulate.p.value = TRUE, B = 1e5) # also close to 0.78

## 6th example in Mehta & Patel's JASA paper
MP6 <- rbind(
  c(1,2,2,1,1,0,1),
  c(2,0,0,2,3,0,0),
  c(0,1,1,1,2,7,3),
  c(1,1,2,0,0,0,1),
  c(0,1,1,1,1,0,0))
fisher.test(MP6)
# Exactly the same p-value, as Cochran's conditions are not met:
fisher.test(MP6, hybrid = TRUE)
```

---

fitted

---

*Extract Model Fitted Values*

---

## Description

fitted is a generic function which extracts fitted values from objects returned by modeling functions. fitted.values is an alias for it.

All object classes which are returned by model fitting functions should provide a fitted method. (Note that the generic is fitted and not fitted.values.)

Methods can make use of [napredict](#) methods to compensate for the omission of missing values. The default and [nls](#) methods do.

## Usage

```
fitted(object, ...)
fitted.values(object, ...)
```

**Arguments**

object            an object for which the extraction of model fitted values is meaningful.  
...               other arguments.

**Value**

Fitted values extracted from the object object.

**References**

---

fivenum

*Tukey Five-Number Summaries*

---

**Description**

Returns Tukey's five number summary (minimum, lower-hinge, median, upper-hinge, maximum) for the input data.

**Usage**

```
fivenum(x, na.rm = TRUE)
```

**Arguments**

x                    numeric, maybe including [NAs](#) and  $\pm$ [Infs](#).  
na.rm               logical; if TRUE, all [NA](#) and [NaNs](#) are dropped, before the statistics are computed.

**Value**

A numeric vector of length 5 containing the summary information. See [boxplot.stats](#) for more details.

**See Also**

[IQR](#), [boxplot.stats](#), [median](#), [quantile](#), [range](#).

**Examples**

```
fivenum(c(rnorm(100), -1:1/0))
```

fligner.test

*Fligner-Killeen Test of Homogeneity of Variances***Description**

Performs a Fligner-Killeen (median) test of the null that the variances in each of the groups (samples) are the same.

**Usage**

```
fligner.test(x, ...)

## Default S3 method:
fligner.test(x, g, ...)

## S3 method for class 'formula'
fligner.test(formula, data, subset, na.action, ...)
```

**Arguments**

|                        |                                                                                                                                                                                                                            |
|------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>         | a numeric vector of data values, or a list of numeric data vectors.                                                                                                                                                        |
| <code>g</code>         | a vector or factor object giving the group for the corresponding elements of <code>x</code> . Ignored if <code>x</code> is a list.                                                                                         |
| <code>formula</code>   | a formula of the form <code>lhs ~ rhs</code> where <code>lhs</code> gives the data values and <code>rhs</code> the corresponding groups.                                                                                   |
| <code>data</code>      | an optional matrix or data frame (or similar: see <a href="#">model.frame</a> ) containing the variables in the formula <code>formula</code> . By default the variables are taken from <code>environment(formula)</code> . |
| <code>subset</code>    | an optional vector specifying a subset of observations to be used.                                                                                                                                                         |
| <code>na.action</code> | a function which indicates what should happen when the data contain NAs. Defaults to <code>getOption("na.action")</code> .                                                                                                 |
| <code>...</code>       | further arguments to be passed to or from methods.                                                                                                                                                                         |

**Details**

If `x` is a list, its elements are taken as the samples to be compared for homogeneity of variances, and hence have to be numeric data vectors. In this case, `g` is ignored, and one can simply use `fligner.test(x)` to perform the test. If the samples are not yet contained in a list, use `fligner.test(list(x, ...))`.

Otherwise, `x` must be a numeric data vector, and `g` must be a vector or factor object of the same length as `x` giving the group for the corresponding elements of `x`.

The Fligner-Killeen (median) test has been determined in a simulation study as one of the many tests for homogeneity of variances which is most robust against departures from normality, see Conover, Johnson & Johnson (1981). It is a  $k$ -sample simple linear rank which uses the ranks of the absolute values of the centered samples and weights  $a(i) = \text{qnorm}((1 + i/(n+1))/2)$ . The version implemented here uses median centering in each of the samples (F-K:med  $X^2$  in the reference).

**Value**

A list of class "htest" containing the following components:

|           |                                                                                           |
|-----------|-------------------------------------------------------------------------------------------|
| statistic | the Fligner-Killeen:med $X^2$ test statistic.                                             |
| parameter | the degrees of freedom of the approximate chi-squared distribution of the test statistic. |
| p.value   | the p-value of the test.                                                                  |
| method    | the character string "Fligner-Killeen test of homogeneity of variances".                  |
| data.name | a character string giving the names of the data.                                          |

**Examples**

```
require(graphics)

plot(count ~ spray, data = InsectSprays)
fligner.test(InsectSprays$count, InsectSprays$spray)
fligner.test(count ~ spray, data = InsectSprays)
## Compare this to bartlett.test()
```

---

|         |                       |
|---------|-----------------------|
| formula | <i>Model Formulae</i> |
|---------|-----------------------|

---

**Description**

The generic function `formula` and its specific methods provide a way of extracting formulae which have been included in other objects.

`as.formula` is almost identical, additionally preserving attributes when object already inherits from "formula".

**Usage**

```
formula(x, ...)
DF2formula(x, env = parent.frame())
as.formula(object, env = parent.frame())

## S3 method for class 'formula'
print(x, showEnv = !identical(e, .GlobalEnv), ...)
```

## Arguments

|                         |                                                                         |
|-------------------------|-------------------------------------------------------------------------|
| <code>x</code> , object | R object, for <code>DF2formula()</code> a <code>data.frame</code> .     |
| <code>...</code>        | further arguments passed to or from other methods.                      |
| <code>env</code>        | the environment to associate with the result, if not already a formula. |
| <code>showEnv</code>    | logical indicating if the environment should be printed as well.        |

## Details

The models fitted by, e.g., the `lm` and `glm` functions are specified in a compact symbolic form. The `~` operator is basic in the formation of such models. An expression of the form `y ~ model` is interpreted as a specification that the response `y` is modelled by a linear predictor specified symbolically by `model`. Such a model consists of a series of terms separated by `+` operators. The terms themselves consist of variable and factor names separated by `:` operators. Such a term is interpreted as the interaction of all the variables and factors appearing in the term.

In addition to `+` and `:`, a number of other operators are useful in model formulae.

- The `*` operator denotes factor crossing: `a*b` is interpreted as `a + b + a:b`.
- The `^` operator indicates crossing to the specified degree. For example `(a+b+c)^2` is identical to `(a+b+c)*(a+b+c)` which in turn expands to a formula containing the main effects for `a`, `b` and `c` together with their second-order interactions.
- The `%in%` operator indicates that the terms on its left are nested within those on the right. For example `a + b %in% a` expands to the formula `a + a:b`.
- The `/` operator provides a shorthand, so that `a / b` is equivalent to `a + b %in% a`.
- The `-` operator removes the specified terms, hence `(a+b+c)^2 - a:b` is identical to `a + b + c + b:c + a:c`. It can also be used to remove the intercept term: when fitting a linear model `y ~ x - 1` specifies a line through the origin. A model with no intercept can be also specified as `y ~ x + 0` or `y ~ 0 + x`.

While formulae usually involve just variable and factor names, they can also involve arithmetic expressions. The formula `log(y) ~ a + log(x)` is quite legal. When such arithmetic expressions involve operators which are also used symbolically in model formulae, there can be confusion between arithmetic and symbolic operator use.

To avoid this confusion, the function `I()` can be used to bracket those portions of a model formula where the operators are used in their arithmetic sense. For example, in the formula `y ~ a + I(b+c)`, the term `b+c` is to be interpreted as the sum of `b` and `c`.

Variable names can be quoted by backticks `like this` in formulae, although there is no guarantee that all code using formulae will accept such non-syntactic names.

Most model-fitting functions accept formulae with right-hand side containing calls to function `offset`. These calls indicate terms with coefficient fixed to one. Some model-fitting functions recognize other “specials” like `strata` and `cluster` (typically by setting the `specials` argument of `terms.formula`). Because specials are nothing more than syntax, disambiguation using `::` or similar is nonsense (even if packages happen to define so-named functions) and the result is often a model that the user does not intend. For example, the formula `y ~ stats::offset(w) + x` does *not* specify a model in which the coefficient of `w` is fixed to one.

There are two special interpretations of `.` in a formula. The usual one is in the context of a data argument of model fitting functions and means ‘all columns not otherwise in the formula’: see `terms.formula`. In the context of `update.formula`, **only**, it means ‘what was previously in this part of the formula’.

When `formula` is called on a fitted model object, either a specific method is used (such as that for class "nls") or the default method. The default first looks for a "formula" component of the object (and evaluates it), then a "terms" component, then a formula parameter of the call (and evaluates its value) and finally a "formula" attribute.

There is a `formula` method for data frames. When there's "terms" attribute with a formula, e.g., for a `model.frame()`, that formula is returned. If you'd like the previous ( $R \leq 3.5.x$ ) behavior, use the auxiliary `DF2formula()` which does not consider a "terms" attribute. Otherwise, if there is only one column this forms the RHS with an empty LHS. For more columns, the first column is the LHS of the formula and the remaining columns separated by `+` form the RHS.

## Value

All the functions above produce an object of class "formula" which contains a symbolic model formula.

## Environments

A formula object has an associated environment, and this environment (rather than the parent environment) is used by `model.frame` to evaluate variables that are not found in the supplied data argument.

Formulas created with the `~` operator use the environment in which they were created. Formulas created with `as.formula` will use the `env` argument for their environment.

## Note

In  $R$  versions up to 3.6.0, `character` `x` of length more than one were parsed as separate lines of  $R$  code and the first complete expression was evaluated into a formula when possible. This silently truncates such vectors of characters inefficiently and to some extent inconsistently as this behaviour had been undocumented. For this reason, such use has been deprecated. If you must work via character `x`, do use a string, i.e., a character vector of length one.

E.g., `eval(call("~", quote(foo + bar)))` has been an order of magnitude more efficient than `formula(c("~", "foo + bar"))`.

Further, character "expressions" needing an `eval()` to return a formula are now deprecated.

friedman.test

*Friedman Rank Sum Test***Description**

Performs a Friedman rank sum test with unreplicated blocked data.

**Usage**

```
friedman.test(y, ...)

## Default S3 method:
friedman.test(y, groups, blocks, ...)

## S3 method for class 'formula'
friedman.test(formula, data, subset, na.action, ...)
```

**Arguments**

|                        |                                                                                                                                                                                                                            |
|------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>y</code>         | either a numeric vector of data values, or a data matrix.                                                                                                                                                                  |
| <code>groups</code>    | a vector giving the group for the corresponding elements of <code>y</code> if this is a vector; ignored if <code>y</code> is a matrix. If not a factor object, it is coerced to one.                                       |
| <code>blocks</code>    | a vector giving the block for the corresponding elements of <code>y</code> if this is a vector; ignored if <code>y</code> is a matrix. If not a factor object, it is coerced to one.                                       |
| <code>formula</code>   | a formula of the form <code>a ~ b   c</code> , where <code>a</code> , <code>b</code> and <code>c</code> give the data values and corresponding groups and blocks, respectively.                                            |
| <code>data</code>      | an optional matrix or data frame (or similar: see <a href="#">model.frame</a> ) containing the variables in the formula <code>formula</code> . By default the variables are taken from <code>environment(formula)</code> . |
| <code>subset</code>    | an optional vector specifying a subset of observations to be used.                                                                                                                                                         |
| <code>na.action</code> | a function which indicates what should happen when the data contain NAs. Defaults to <code>getOption("na.action")</code> .                                                                                                 |
| <code>...</code>       | further arguments to be passed to or from methods.                                                                                                                                                                         |

**Details**

`friedman.test` can be used for analyzing unreplicated complete block designs (i.e., there is exactly one observation in `y` for each combination of levels of groups and blocks) where the normality assumption may be violated.

The null hypothesis is that apart from an effect of blocks, the location parameter of `y` is the same in each of the groups.

If `y` is a matrix, `groups` and `blocks` are obtained from the column and row indices, respectively. NA's are not allowed in `groups` or `blocks`; if `y` contains NA's, corresponding blocks are removed.

**Value**

A list with class "htest" containing the following components:

|           |                                                                                           |
|-----------|-------------------------------------------------------------------------------------------|
| statistic | the value of Friedman's chi-squared statistic.                                            |
| parameter | the degrees of freedom of the approximate chi-squared distribution of the test statistic. |
| p.value   | the p-value of the test.                                                                  |
| method    | the character string "Friedman rank sum test".                                            |
| data.name | a character string giving the names of the data.                                          |

ftable

*Flat Contingency Tables*

## Description

Create ‘flat’ contingency tables.

## Usage

```
ftable(x, ...)
```

```
## Default S3 method:
```

```
ftable(..., exclude = c(NA, NaN), row.vars = NULL,
       col.vars = NULL)
```

## Arguments

|                       |                                                                                                                                                                                                            |
|-----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x, ...</code>   | R objects which can be interpreted as factors (including character strings), or a list (or data frame) whose components can be so interpreted, or a contingency table object of class "table" or "ftable". |
| <code>exclude</code>  | values to use in the exclude argument of factor when interpreting non-factor objects.                                                                                                                      |
| <code>row.vars</code> | a vector of integers giving the numbers of the variables, or a character vector giving the names of the variables to be used for the rows of the flat contingency table.                                   |
| <code>col.vars</code> | a vector of integers giving the numbers of the variables, or a character vector giving the names of the variables to be used for the columns of the flat contingency table.                                |

## Details

ftable creates ‘flat’ contingency tables. Similar to the usual contingency tables, these contain the counts of each combination of the levels of the variables (factors) involved. This information is then re-arranged as a matrix whose rows and columns correspond to unique combinations of the levels of the row and column variables (as specified by `row.vars` and `col.vars`, respectively). The combinations are created by looping over the variables in reverse order (so that the levels of the left-most variable vary the slowest). Displaying a contingency table in this flat matrix form (via `print.ftable`, the print method for objects of class "ftable") is often preferable to showing it as a higher-dimensional array.

`ftable` is a generic function. Its default method, `ftable.default`, first creates a contingency table in array form from all arguments except `row.vars` and `col.vars`. If the first argument is of class `"table"`, it represents a contingency table and is used as is; if it is a flat table of class `"ftable"`, the information it contains is converted to the usual array representation using `as.table`. Otherwise, the arguments should be R objects which can be interpreted as factors (including character strings), or a list (or data frame) whose components can be so interpreted, which are cross-tabulated using `table`. Then, the arguments `row.vars` and `col.vars` are used to collapse the contingency table into flat form. If neither of these two is given, the last variable is used for the columns. If both are given and their union is a proper subset of all variables involved, the other variables are summed out.

When the arguments are R expressions interpreted as factors, additional arguments will be passed to `table` to control how the variable names are displayed; see the last example below.

Function `ftable.formula` provides a formula method for creating flat contingency tables.

There are methods for `as.table`, `as.matrix` and `as.data.frame`.

## Value

`ftable` returns an object of class `"ftable"`, which is a matrix with counts of each combination of the levels of variables with information on the names and levels of the (row and columns) variables stored as attributes `"row.vars"` and `"col.vars"`.

## See Also

`ftable.formula` for the formula interface (which allows a `data = .` argument); `read.ftable` for information on reading, writing and coercing flat contingency tables; `table` for ordinary cross-tabulation; `xtabs` for formula-based cross-tabulation.

## Examples

```
## Start with a contingency table.
ftable(Titanic, row.vars = 1:3)
ftable(Titanic, row.vars = 1:2, col.vars = "Survived")
ftable(Titanic, row.vars = 2:1, col.vars = "Survived")

## Start with a data frame.
x <- ftable(mtcars[c("cyl", "vs", "am", "gear")])
x
ftable(x, row.vars = c(2, 4))

## Start with expressions, use table()'s "dnn" to change labels
ftable(mtcars$cyl, mtcars$vs, mtcars$am, mtcars$gear, row.vars = c(2, 4),
       dnn = c("Cylinders", "V/S", "Transmission", "Gears"))
```

---

`ftable.formula`

*Formula Notation for Flat Contingency Tables*

---

## Description

Produce or manipulate a flat contingency table using formula notation.

**Usage**

```
## S3 method for class 'formula'
fable(formula, data = NULL, subset, na.action, ...)
```

**Arguments**

|           |                                                                                                                                                                      |
|-----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| formula   | a formula object with both left and right hand sides specifying the column and row variables of the flat table.                                                      |
| data      | a data frame, list or environment (or similar: see <a href="#">model.frame</a> ) containing the variables to be cross-tabulated, or a contingency table (see below). |
| subset    | an optional vector specifying a subset of observations to be used. Ignored if data is a contingency table.                                                           |
| na.action | a function which indicates what should happen when the data contain NAs. Ignored if data is a contingency table.                                                     |
| ...       | further arguments to the default ftable method may also be passed as arguments, see <a href="#">fable.default</a> .                                                  |

**Details**

This is a method of the generic function [fable](#).

The left and right hand side of formula specify the column and row variables, respectively, of the flat contingency table to be created. Only the + operator is allowed for combining the variables. A . may be used once in the formula to indicate inclusion of all the remaining variables.

If data is an object of class "table" or an array with more than 2 dimensions, it is taken as a contingency table, and hence all entries should be nonnegative. Otherwise, if it is not a flat contingency table (i.e., an object of class "ftable"), it should be a data frame or matrix, list or environment containing the variables to be cross-tabulated. In this case, na.action is applied to the data to handle missing values, and, after possibly selecting a subset of the data as specified by the subset argument, a contingency table is computed from the variables.

The contingency table is then collapsed to a flat table, according to the row and column variables specified by formula.

**Value**

A flat contingency table which contains the counts of each combination of the levels of the variables, collapsed into a matrix for suitably displaying the counts.

**See Also**

[fable](#), [fable.default](#); [table](#).

**Examples**

```
Titanic
x <- ftable(Survived ~ ., data = Titanic)
x
fable(Sex ~ Class + Age, data = x)
```

## Description

Density, distribution function, quantile function and random generation for the Gamma distribution with parameters shape and scale.

## Usage

```
dgamma(x, shape, rate = 1, scale = 1/rate, log = FALSE)
pgamma(q, shape, rate = 1, scale = 1/rate, lower.tail = TRUE,
       log.p = FALSE)
qgamma(p, shape, rate = 1, scale = 1/rate, lower.tail = TRUE,
       log.p = FALSE)
rgamma(n, shape, rate = 1, scale = 1/rate)
```

## Arguments

|              |                                                                                          |
|--------------|------------------------------------------------------------------------------------------|
| x, q         | vector of quantiles.                                                                     |
| p            | vector of probabilities.                                                                 |
| n            | number of observations. If length(n) > 1, the length is taken to be the number required. |
| rate         | an alternative way to specify the scale.                                                 |
| shape, scale | shape and scale parameters. Must be positive, scale strictly.                            |
| log, log.p   | logical; if TRUE, probabilities/densities $p$ are returned as $\log(p)$ .                |
| lower.tail   | logical; if TRUE (default), probabilities are $P[X \leq x]$ , otherwise, $P[X > x]$ .    |

## Details

If scale is omitted, it assumes the default value of 1.

The Gamma distribution with parameters shape =  $\alpha$  and scale =  $\sigma$  has density

$$f(x) = \frac{1}{\sigma^\alpha \Gamma(\alpha)} x^{\alpha-1} e^{-x/\sigma}$$

for  $x \geq 0$ ,  $\alpha > 0$  and  $\sigma > 0$ . (Here  $\Gamma(\alpha)$  is the function implemented by R's `gamma()` and defined in its help. Note that  $\alpha = 0$  corresponds to the trivial distribution with all mass at point 0.)

The mean and variance are  $E(X) = \alpha\sigma$  and  $Var(X) = \alpha\sigma^2$ .

The cumulative hazard  $H(t) = -\log(1 - F(t))$  is

```
-pgamma(t, ..., lower = FALSE, log = TRUE)
```

Note that for smallish values of shape (and moderate scale) a large parts of the mass of the Gamma distribution is on values of  $x$  so near zero that they will be represented as zero in computer arithmetic. So `rgamma` may well return values which will be represented as zero. (This will also happen for very large values of scale since the actual generation is done for scale = 1.)

**Value**

dgamma gives the density, pgamma gives the distribution function, qgamma gives the quantile function, and rgamma generates random deviates.

Invalid arguments will result in return value NaN, with a warning.

The length of the result is determined by n for rgamma, and is the maximum of the lengths of the numerical arguments for the other functions.

The numerical arguments other than n are recycled to the length of the result. Only the first elements of the logical arguments are used.

**Note**

The S (Becker et al., 1988) parametrization was via shape and rate: S had no scale parameter. It is an error to supply both scale and rate.

pgamma is closely related to the incomplete gamma function. As defined by Abramowitz and Stegun 6.5.1 (and by ‘Numerical Recipes’) this is

$$P(a, x) = \frac{1}{\Gamma(a)} \int_0^x t^{a-1} e^{-t} dt$$

$P(a, x)$  is pgamma(x, a). Other authors (for example Karl Pearson in his 1922 tables) omit the normalizing factor, defining the incomplete gamma function  $\gamma(a, x)$  as  $\gamma(a, x) = \int_0^x t^{a-1} e^{-t} dt$ , i.e., pgamma(x, a) \* gamma(a). Yet other use the ‘upper’ incomplete gamma function,

$$\Gamma(a, x) = \int_x^\infty t^{a-1} e^{-t} dt,$$

which can be computed by pgamma(x, a, lower = FALSE) \* gamma(a).

Note however that pgamma(x, a, .) currently requires  $a > 0$ , whereas the incomplete gamma function is also defined for negative  $a$ . In that case, you can use gamma\_inc(a, x) (for  $\Gamma(a, x)$ ) from package **gsl**.

See also [https://en.wikipedia.org/wiki/Incomplete\\_gamma\\_function](https://en.wikipedia.org/wiki/Incomplete_gamma_function), or <https://dlmf.nist.gov/8.2#i>.

**Source**

dgamma is computed via the Poisson density, using code contributed by Catherine Loader (see [dbinom](#)).

pgamma uses an unpublished (and not otherwise documented) algorithm ‘mainly by Morten Welinder’.

qgamma is based on a C translation of

Best, D. J. and D. E. Roberts (1975). Algorithm AS91. Percentage points of the chi-squared distribution. *Applied Statistics*, **24**, 385–388.

plus a final Newton step to improve the approximation.

rgamma for shape  $\geq 1$  uses

Ahrens, J. H. and Dieter, U. (1982). Generating gamma variates by a modified rejection technique. *Communications of the ACM*, **25**, 47–54,

and for  $0 < \text{shape} < 1$  uses

Ahrens, J. H. and Dieter, U. (1974). Computer methods for sampling from gamma, beta, Poisson and binomial distributions. *Computing*, **12**, 223–246.

Geometric

*The Geometric Distribution*

---

## Description

Density, distribution function, quantile function and random generation for the geometric distribution with parameter prob.

## Usage

```
dgeom(x, prob, log = FALSE)
pgeom(q, prob, lower.tail = TRUE, log.p = FALSE)
qgeom(p, prob, lower.tail = TRUE, log.p = FALSE)
rgeom(n, prob)
```

## Arguments

- |      |                                                                                                                  |
|------|------------------------------------------------------------------------------------------------------------------|
| x, q | vector of quantiles representing the number of failures in a sequence of Bernoulli trials before success occurs. |
| p    | vector of probabilities.                                                                                         |

|                         |                                                                                                           |
|-------------------------|-----------------------------------------------------------------------------------------------------------|
| <code>n</code>          | number of observations. If <code>length(n) &gt; 1</code> , the length is taken to be the number required. |
| <code>prob</code>       | probability of success in each trial. $0 < \text{prob} \leq 1$ .                                          |
| <code>log, log.p</code> | logical; if TRUE, probabilities <code>p</code> are given as <code>log(p)</code> .                         |
| <code>lower.tail</code> | logical; if TRUE (default), probabilities are $P[X \leq x]$ , otherwise, $P[X > x]$ .                     |

### Details

The geometric distribution with  $\text{prob} = p$  has density

$$p(x) = p(1 - p)^x$$

for  $x = 0, 1, 2, \dots$ ,  $0 < p \leq 1$ .

If an element of `x` is not integer, the result of `dgeom` is zero, with a warning.

The quantile is defined as the smallest value  $x$  such that  $F(x) \geq p$ , where  $F$  is the distribution function.

### Value

`dgeom` gives the density, `pgeom` gives the distribution function, `qgeom` gives the quantile function, and `rgeom` generates random deviates.

Invalid `prob` will result in return value `NaN`, with a warning.

The length of the result is determined by `n` for `rgeom`, and is the maximum of the lengths of the numerical arguments for the other functions.

The numerical arguments other than `n` are recycled to the length of the result. Only the first elements of the logical arguments are used.

`rgeom` returns a vector of type [integer](#) unless generated values exceed the maximum representable integer when [double](#) values are returned.

### Source

`dgeom` computes via `dbinom`, using code contributed by Catherine Loader (see [dbinom](#)).

`pgeom` and `qgeom` are based on the closed-form formulae.

`rgeom` uses the derivation as an exponential mixture of Poisson distributions, see

Devroye, L. (1986) *Non-Uniform Random Variate Generation*. Springer-Verlag, New York. Page 480.

### See Also

[Distributions](#) for other standard distributions, including [dnbinom](#) for the negative binomial which generalizes the geometric distribution.

### Examples

```
qgeom((1:9)/10, prob = .2)
Ni <- rgeom(20, prob = 1/4); table(factor(Ni, 0:max(Ni)))
```

---

getInitial

*Get Initial Parameter Estimates*

---

## Description

This function evaluates initial parameter estimates for a nonlinear regression model. If data is a parameterized data frame or pframe object, its parameters attribute is returned. Otherwise the object is examined to see if it contains a call to a selfStart object whose initial attribute can be evaluated.

## Usage

```
getInitial(object, data, ...)
```

## Arguments

|        |                                                                                                           |
|--------|-----------------------------------------------------------------------------------------------------------|
| object | a formula or a <a href="#">selfStart</a> model that defines a nonlinear regression model                  |
| data   | a data frame in which the expressions in the formula or arguments to the selfStart model can be evaluated |
| ...    | optional additional arguments                                                                             |

## Value

A named numeric vector or list of starting estimates for the parameters. The construction of many selfStart models is such that these "starting" estimates are, in fact, the converged parameter estimates.

## Author(s)

José Pinheiro and Douglas Bates

PurTrt <- Puromycin[ Puromycin$state == "treated", ]
print(getInitial( rate ~ SSmicmen( conc, Vm, K ), PurTrt ), digits = 3)
```

glm

*Fitting Generalized Linear Models***Description**

glm is used to fit generalized linear models, specified by giving a symbolic description of the linear predictor and a description of the error distribution.

**Usage**

```
glm(formula, family = gaussian, data, weights, subset,
    na.action, start = NULL, etastart, mustart, offset,
    control = list(...), model = TRUE, method = "glm.fit",
    x = FALSE, y = TRUE, singular.ok = TRUE, contrasts = NULL, ...)

glm.fit(x, y, weights = rep.int(1, nobs),
    start = NULL, etastart = NULL, mustart = NULL,
    offset = rep.int(0, nobs), family = gaussian(),
    control = list(), intercept = TRUE, singular.ok = TRUE)

## S3 method for class 'glm'
weights(object, type = c("prior", "working"), ...)
```

**Arguments**

|           |                                                                                                                                                                                                                                                                                                                                                        |
|-----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| formula   | an object of class " <a href="#">formula</a> " (or one that can be coerced to that class): a symbolic description of the model to be fitted. The details of model specification are given under ‘Details’.                                                                                                                                             |
| family    | a description of the error distribution and link function to be used in the model. For glm this can be a character string naming a family function, a family function or the result of a call to a family function. For glm.fit only the third option is supported. (See <a href="#">family</a> for details of family functions.)                      |
| data      | an optional data frame, list or environment (or object coercible by <a href="#">as.data.frame</a> to a data frame) containing the variables in the model. If not found in data, the variables are taken from environment(formula), typically the environment from which glm is called.                                                                 |
| weights   | an optional vector of ‘prior weights’ to be used in the fitting process. Should be NULL or a numeric vector.                                                                                                                                                                                                                                           |
| subset    | an optional vector specifying a subset of observations to be used in the fitting process.                                                                                                                                                                                                                                                              |
| na.action | a function which indicates what should happen when the data contain NAs. The default is set by the na.action setting of <a href="#">options</a> , and is <a href="#">na.fail</a> if that is unset. The ‘factory-fresh’ default is <a href="#">na.omit</a> . Another possible value is NULL, no action. Value <a href="#">na.exclude</a> can be useful. |
| start     | starting values for the parameters in the linear predictor.                                                                                                                                                                                                                                                                                            |
| etastart  | starting values for the linear predictor.                                                                                                                                                                                                                                                                                                              |
| mustart   | starting values for the vector of means.                                                                                                                                                                                                                                                                                                               |

|             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|-------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| offset      | this can be used to specify an <i>a priori</i> known component to be included in the linear predictor during fitting. This should be NULL or a numeric vector of length equal to the number of cases. One or more <code>offset</code> terms can be included in the formula instead or as well, and if more than one is specified their sum is used. See <code>model.offset</code> .                                                                                                                                      |
| control     | a list of parameters for controlling the fitting process. For <code>glm.fit</code> this is passed to <code>glm.control</code> .                                                                                                                                                                                                                                                                                                                                                                                          |
| model       | a logical value indicating whether <i>model frame</i> should be included as a component of the returned value.                                                                                                                                                                                                                                                                                                                                                                                                           |
| method      | the method to be used in fitting the model. The default method " <code>glm.fit</code> " uses iteratively reweighted least squares (IWLS); the alternative " <code>model.frame</code> " returns the model frame and does no fitting.<br>User-supplied fitting functions can be supplied either as a function or a character string naming a function, with a function which takes the same arguments as <code>glm.fit</code> . If specified as a character string it is looked up from within the <b>stats</b> namespace. |
| x, y        | For <code>glm</code> : logical values indicating whether the response vector and model matrix used in the fitting process should be returned as components of the returned value.<br>For <code>glm.fit</code> : <code>x</code> is a design matrix of dimension $n * p$ , and <code>y</code> is a vector of observations of length $n$ .                                                                                                                                                                                  |
| singular.ok | logical; if FALSE a singular fit is an error.                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| contrasts   | an optional list. See the <code>contrasts.arg</code> of <code>model.matrix.default</code> .                                                                                                                                                                                                                                                                                                                                                                                                                              |
| intercept   | logical. Should an intercept be included in the <i>null</i> model?                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| object      | an object inheriting from class " <code>glm</code> ".                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| type        | character, partial matching allowed. Type of weights to extract from the fitted model object. Can be abbreviated.                                                                                                                                                                                                                                                                                                                                                                                                        |
| ...         | For <code>glm</code> : arguments to be used to form the default <code>control</code> argument if it is not supplied directly.<br>For weights: further arguments passed to or from other methods.                                                                                                                                                                                                                                                                                                                         |

## Details

A typical predictor has the form `response ~ terms` where `response` is the (numeric) response vector and `terms` is a series of terms which specifies a linear predictor for response. For binomial and quasibinomial families the response can also be specified as a **factor** (when the first level denotes failure and all others success) or as a two-column matrix with the columns giving the numbers of successes and failures. A terms specification of the form `first + second` indicates all the terms in `first` together with all the terms in `second` with any duplicates removed.

A specification of the form `first:second` indicates the set of terms obtained by taking the interactions of all terms in `first` with all terms in `second`. The specification `first*second` indicates the *cross* of `first` and `second`. This is the same as `first + second + first:second`.

The terms in the formula will be re-ordered so that main effects come first, followed by the interactions, all second-order, all third-order and so on: to avoid this pass a `terms` object as the formula.

Non-NULL weights can be used to indicate that different observations have different dispersions (with the values in `weights` being inversely proportional to the dispersions); or equivalently, when the elements of `weights` are positive integers  $w_i$ , that each response  $y_i$  is the mean of  $w_i$  unit-weight observations. For a binomial GLM prior weights are used to give the number of trials when the response is the proportion of successes: they would rarely be used for a Poisson GLM.

`glm.fit` is the workhorse function: it is not normally called directly but can be more efficient where the response vector, design matrix and family have already been calculated.

If more than one of `etastart`, `start` and `mustart` is specified, the first in the list will be used. It is often advisable to supply starting values for a [quasi](#) family, and also for families with unusual links such as `gaussian("log")`.

All of `weights`, `subset`, `offset`, `etastart` and `mustart` are evaluated in the same way as variables in formula, that is first in data and then in the environment of formula.

For the background to warning messages about ‘fitted probabilities numerically 0 or 1 occurred’ for binomial GLMs, see Venables & Ripley (2002, pp. 197–8).

## Value

`glm` returns an object of class inheriting from `"glm"` which inherits from the class `"lm"`. See later in this section. If a non-standard method is used, the object will also inherit from the class (if any) returned by that function.

The function `summary` (i.e., `summary.glm`) can be used to obtain or print a summary of the results and the function `anova` (i.e., `anova.glm`) to produce an analysis of variance table.

The generic accessor functions `coefficients`, `effects`, `fitted.values` and `residuals` can be used to extract various useful features of the value returned by `glm`.

`weights` extracts a vector of weights, one for each case in the fit (after subsetting and `na.action`).

An object of class `"glm"` is a list containing at least the following components:

|                                |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|--------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>coefficients</code>      | a named vector of coefficients                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <code>residuals</code>         | the <i>working</i> residuals, that is the residuals in the final iteration of the IWLS fit. Since cases with zero weights are omitted, their working residuals are NA.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <code>fitted.values</code>     | the fitted mean values, obtained by transforming the linear predictors by the inverse of the link function.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <code>rank</code>              | the numeric rank of the fitted linear model.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <code>family</code>            | the <a href="#">family</a> object used.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <code>linear.predictors</code> | the linear fit on link scale.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <code>deviance</code>          | up to a constant, minus twice the maximized log-likelihood. Where sensible, the constant is chosen so that a saturated model has deviance zero.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <code>aic</code>               | A version of Akaike’s <i>An Information Criterion</i> , minus twice the maximized log-likelihood plus twice the number of parameters, computed via the <code>aic</code> component of the family. For binomial and Poisson families the dispersion is fixed at one and the number of parameters is the number of coefficients. For gaussian, Gamma and inverse gaussian families the dispersion is estimated from the residual deviance, and the number of parameters is the number of coefficients plus one. For a gaussian family the MLE of the dispersion is used so this is a valid value of AIC, but for Gamma and inverse gaussian families it is not. For families fitted by quasi-likelihood the value is NA. |
| <code>null.deviance</code>     | The deviance for the null model, comparable with deviance. The null model will include the offset, and an intercept if there is one in the model. Note that this will be incorrect if the link function depends on the data other than through the fitted mean: specify a zero offset to force a correct calculation.                                                                                                                                                                                                                                                                                                                                                                                                 |
| <code>iter</code>              | the number of iterations of IWLS used.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <code>weights</code>           | the <i>working</i> weights, that is the weights in the final iteration of the IWLS fit.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

|                            |                                                                                                                                                                             |
|----------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>prior.weights</code> | the weights initially supplied, a vector of 1s if none were.                                                                                                                |
| <code>df.residual</code>   | the residual degrees of freedom.                                                                                                                                            |
| <code>df.null</code>       | the residual degrees of freedom for the null model.                                                                                                                         |
| <code>y</code>             | if requested (the default) the y vector used. (It is a vector even for a binomial model.)                                                                                   |
| <code>x</code>             | if requested, the model matrix.                                                                                                                                             |
| <code>model</code>         | if requested (the default), the model frame.                                                                                                                                |
| <code>converged</code>     | logical. Was the IWLS algorithm judged to have converged?                                                                                                                   |
| <code>boundary</code>      | logical. Is the fitted value on the boundary of the attainable values?                                                                                                      |
| <code>call</code>          | the matched call.                                                                                                                                                           |
| <code>formula</code>       | the formula supplied.                                                                                                                                                       |
| <code>terms</code>         | the <code>terms</code> object used.                                                                                                                                         |
| <code>data</code>          | the data argument.                                                                                                                                                          |
| <code>offset</code>        | the offset vector used.                                                                                                                                                     |
| <code>control</code>       | the value of the control argument used.                                                                                                                                     |
| <code>method</code>        | the name of the fitter function used (when provided as a <code>character</code> string to <code>glm()</code> ) or the fitter <code>function</code> (when provided as that). |
| <code>contrasts</code>     | (where relevant) the contrasts used.                                                                                                                                        |
| <code>xlevels</code>       | (where relevant) a record of the levels of the factors used in fitting.                                                                                                     |
| <code>na.action</code>     | (where relevant) information returned by <code>model.frame</code> on the special handling of NAs.                                                                           |

In addition, non-empty fits will have components `qr`, `R` and `effects` relating to the final weighted linear fit.

Objects of class `"glm"` are normally of class `c("glm", "lm")`, that is inherit from class `"lm"`, and well-designed methods for class `"lm"` will be applied to the weighted linear model at the final iteration of IWLS. However, care is needed, as extractor functions for class `"glm"` such as `residuals` and `weights` do **not** just pick out the component of the fit with the same name.

If a `binomial` `glm` model was specified by giving a two-column response, the weights returned by `prior.weights` are the total numbers of cases (factored by the supplied case weights) and the component `y` of the result is the proportion of successes.

### Fitting functions

The argument `method` serves two purposes. One is to allow the model frame to be recreated with no fitting. The other is to allow the default fitting function `glm.fit` to be replaced by a function which takes the same arguments and uses a different fitting algorithm. If `glm.fit` is supplied as a character string it is used to search for a function of that name, starting in the `stats` namespace.

The class of the object return by the fitter (if any) will be prepended to the class returned by `glm`.

### Author(s)

The original R implementation of `glm` was written by Simon Davies working for Ross Ihaka at the University of Auckland, but has since been extensively re-written by members of the R Core team.

The design was inspired by the S function of the same name described in Hastie & Pregibon (1992).

## Dobson (1990) Page 93: Randomized Controlled Trial :
counts <- c(18,17,15,20,10,20,25,13,12)
outcome <- gl(3,1,9)
treatment <- gl(3,3)
data.frame(treatment, outcome, counts) # showing data
glm.D93 <- glm(counts ~ outcome + treatment, family = poisson())
anova(glm.D93)
summary(glm.D93)
## Computing AIC [in many ways]:
(A0 <- AIC(glm.D93))
(l1 <- logLik(glm.D93))
A1 <- -2*c(l1) + 2*attr(l1, "df")
A2 <- glm.D93$family$aic(counts, mu=fitted(glm.D93), wt=1) +
  2 * length(coef(glm.D93))
stopifnot(exprs = {
  all.equal(A0, A1)
  all.equal(A1, A2)
  all.equal(A1, glm.D93$aic)
})
```

```
## an example with offsets from Venables & Ripley (2002, p.189)
utils::data(anorexia, package = "MASS")
```

```
anorex.1 <- glm(Postwt ~ Prewt + Treat + offset(Prewt),
  family = gaussian, data = anorexia)
summary(anorex.1)
```

```
# A Gamma example, from McCullagh & Nelder (1989, pp. 300-2)
clotting <- data.frame(
  u = c(5,10,15,20,30,40,60,80,100),
  lot1 = c(118,58,42,35,27,25,21,19,18),
```

```

lot2 = c(69,35,26,21,18,16,13,12,12))
summary(glm(lot1 ~ log(u), data = clotting, family = Gamma))
summary(glm(lot2 ~ log(u), data = clotting, family = Gamma))
## Aliased ("S"ingular) -> 1 NA coefficient
(fS <- glm(lot2 ~ log(u) + log(u^2), data = clotting, family = Gamma))

glm.control

*Auxiliary for Controlling GLM Fitting*

## Description

Auxiliary function for `glm` fitting. Typically only used internally by `glm.fit`, but may be used to construct a control argument to either function.

## Usage

```
glm.control(epsilon = 1e-8, maxit = 25, trace = FALSE)
```

## Arguments

|                      |                                                                                                                         |
|----------------------|-------------------------------------------------------------------------------------------------------------------------|
| <code>epsilon</code> | positive convergence tolerance $\epsilon$ ; the iterations converge when $ dev - dev_{old} /( dev  + 0.1) < \epsilon$ . |
| <code>maxit</code>   | integer giving the maximal number of IWLS iterations.                                                                   |
| <code>trace</code>   | logical indicating if output should be produced for each iteration.                                                     |

## Details

The control argument of `glm` is by default passed to the control argument of `glm.fit`, which uses its elements as arguments to `glm.control`: the latter provides defaults and sanity checking.

If `epsilon` is small (less than  $10^{-10}$ ) it is also used as the tolerance for the detection of collinearity in the least squares solution.

When `trace` is true, calls to `cat` produce the output for each IWLS iteration. Hence, `options(digits = *)` can be used to increase the precision, see the example.

## Value

A list with components named as the arguments.

**Examples**

```
### A variation on example(glm) :

## Annette Dobson's example ...
counts <- c(18,17,15,20,10,20,25,13,12)
outcome <- gl(3,1,9)
treatment <- gl(3,3)
oo <- options(digits = 12) # to see more when tracing :
glm.D93X <- glm(counts ~ outcome + treatment, family = poisson(),
               trace = TRUE, epsilon = 1e-14)
options(oo)
coef(glm.D93X) # the last two are closer to 0 than in ?glm's glm.D93
```

glm.summaries

*Accessing Generalized Linear Model Fits***Description**

These functions are all [methods](#) for class `glm` or `summary.glm` objects.

**Usage**

```
## S3 method for class 'glm'
family(object, ...)

## S3 method for class 'glm'
residuals(object, type = c("deviance", "pearson", "working",
                          "response", "partial"), ...)
```

**Arguments**

|                     |                                                                                                                                                                  |
|---------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>object</code> | an object of class <code>glm</code> , typically the result of a call to <a href="#">glm</a> .                                                                    |
| <code>type</code>   | the type of residuals which should be returned. The alternatives are: "deviance" (default), "pearson", "working", "response", and "partial". Can be abbreviated. |
| <code>...</code>    | further arguments passed to or from other methods.                                                                                                               |

**Details**

The references define the types of residuals: Davison & Snell is a good reference for the usages of each.

The partial residuals are a matrix of working residuals, with each column formed by omitting a term from the model.

How residuals treats cases with missing values in the original fit is determined by the `na.action` argument of that fit. If `na.action = na.omit` omitted cases will not appear in the residuals, whereas if `na.action = na.exclude` they will appear, with residual value NA. See also [naresid](#).

For fits done with `y = FALSE` the response values are computed from other components.

hclust

*Hierarchical Clustering*

---

## Description

Hierarchical cluster analysis on a set of dissimilarities and methods for analyzing it.

## Usage

```
hclust(d, method = "complete", members = NULL)

## S3 method for class 'hclust'
plot(x, labels = NULL, hang = 0.1, check = TRUE,
     axes = TRUE, frame.plot = FALSE, ann = TRUE,
     main = "Cluster Dendrogram",
     sub = NULL, xlab = NULL, ylab = "Height", ...)
```

## Arguments

|         |                                                                                                                                                                                                                                                                                                                            |
|---------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| d       | a dissimilarity structure as produced by <code>dist</code> .                                                                                                                                                                                                                                                               |
| method  | the agglomeration method to be used. This should be (an unambiguous abbreviation of) one of "ward.D", "ward.D2", "single", "complete", "average" (= UPGMA), "mcquitty" (= WPGMA), "median" (= WPGMC) or "centroid" (= UPGMC).                                                                                              |
| members | NULL or a vector with length size of d. See the 'Details' section.                                                                                                                                                                                                                                                         |
| x       | an object of the type produced by <code>hclust</code> .                                                                                                                                                                                                                                                                    |
| hang    | The fraction of the plot height by which labels should hang below the rest of the plot. A negative value will cause the labels to hang down from 0.                                                                                                                                                                        |
| check   | logical indicating if the x object should be checked for validity. This check is not necessary when x is known to be valid such as when it is the direct result of <code>hclust()</code> . The default is <code>check=TRUE</code> , as invalid inputs may crash R due to memory violation in the internal C plotting code. |

|                       |                                                                                                                                                                                              |
|-----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| labels                | A character vector of labels for the leaves of the tree. By default the row names or row numbers of the original data are used. If <code>labels = FALSE</code> no labels at all are plotted. |
| axes, frame.plot, ann | logical flags as in <code>plot.default</code> .                                                                                                                                              |
| main, sub, xlab, ylab | character strings for <code>title</code> . <code>sub</code> and <code>xlab</code> have a non-NULL default when there's a <code>tree\$call</code> .                                           |
| ...                   | Further graphical arguments. E.g., <code>cex</code> controls the size of the labels (if plotted) in the same way as <code>text</code> .                                                      |

## Details

This function performs a hierarchical cluster analysis using a set of dissimilarities for the  $n$  objects being clustered. Initially, each object is assigned to its own cluster and then the algorithm proceeds iteratively, at each stage joining the two most similar clusters, continuing until there is just a single cluster. At each stage distances between clusters are recomputed by the Lance–Williams dissimilarity update formula according to the particular clustering method being used.

A number of different clustering methods are provided. *Ward's* minimum variance method aims at finding compact, spherical clusters. The *complete linkage* method finds similar clusters. The *single linkage* method (which is closely related to the minimal spanning tree) adopts a ‘friends of friends’ clustering strategy. The other methods can be regarded as aiming for clusters with characteristics somewhere between the single and complete link methods. Note however, that methods “median” and “centroid” are *not* leading to a *monotone distance* measure, or equivalently the resulting dendrograms can have so called *inversions* or *reversals* which are hard to interpret, but note the trichotomies in Legendre and Legendre (2012).

Two different algorithms are found in the literature for Ward clustering. The one used by option “ward.D” (equivalent to the only Ward option “ward” in R versions  $\leq 3.0.3$ ) *does not* implement Ward’s (1963) clustering criterion, whereas option “ward.D2” implements that criterion (Murtagh and Legendre 2014). With the latter, the dissimilarities are *squared* before cluster updating. Note that `agnes(*, method="ward")` corresponds to `hclust(*, "ward.D2")`.

If `members != NULL`, then `d` is taken to be a dissimilarity matrix between clusters instead of dissimilarities between singletons and `members` gives the number of observations per cluster. This way the hierarchical cluster algorithm can be ‘started in the middle of the dendrogram’, e.g., in order to reconstruct the part of the tree above a cut (see examples). Dissimilarities between clusters can be efficiently computed (i.e., without `hclust` itself) only for a limited number of distance/linkage combinations, the simplest one being *squared* Euclidean distance and centroid linkage. In this case the dissimilarities between the clusters are the squared Euclidean distances between cluster means.

In hierarchical cluster displays, a decision is needed at each merge to specify which subtree should go on the left and which on the right. Since, for  $n$  observations there are  $n - 1$  merges, there are  $2^{(n-1)}$  possible orderings for the leaves in a cluster tree, or dendrogram. The algorithm used in `hclust` is to order the subtree so that the tighter cluster is on the left (the last, i.e., most recent, merge of the left subtree is at a lower value than the last merge of the right subtree). Single observations are the tightest clusters possible, and merges involving two observations place them in order by their observation sequence number.

## Value

An object of class “hclust” which describes the tree produced by the clustering process. The object is a list with components:

|             |                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|-------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| merge       | an $n - 1$ by 2 matrix. Row $i$ of merge describes the merging of clusters at step $i$ of the clustering. If an element $j$ in the row is negative, then observation $-j$ was merged at this stage. If $j$ is positive then the merge was with the cluster formed at the (earlier) stage $j$ of the algorithm. Thus negative entries in merge indicate agglomerations of singletons, and positive entries indicate agglomerations of non-singletons. |
| height      | a set of $n - 1$ real values (non-decreasing for ultrametric trees). The clustering <i>height</i> : that is, the value of the criterion associated with the clustering method for the particular agglomeration.                                                                                                                                                                                                                                      |
| order       | a vector giving the permutation of the original observations suitable for plotting, in the sense that a cluster plot using this ordering and matrix merge will not have crossings of the branches.                                                                                                                                                                                                                                                   |
| labels      | labels for each of the objects being clustered.                                                                                                                                                                                                                                                                                                                                                                                                      |
| call        | the call which produced the result.                                                                                                                                                                                                                                                                                                                                                                                                                  |
| method      | the cluster method that has been used.                                                                                                                                                                                                                                                                                                                                                                                                               |
| dist.method | the distance that has been used to create d (only returned if the distance object has a "method" attribute).                                                                                                                                                                                                                                                                                                                                         |

There are `print`, `plot` and `identify` (see `identify.hclust`) methods and the `rect.hclust()` function for `hclust` objects.

### Note

Method "centroid" is typically meant to be used with *squared* Euclidean distances.

### Author(s)

The `hclust` function is based on Fortran code contributed to STATLIB by F. Murtagh.

**Examples**

```
require(graphics)

### Example 1: Violent crime rates by US state

hc <- hclust(dist(USArrests), "ave")
plot(hc)
plot(hc, hang = -1)

## Do the same with centroid clustering and *squared* Euclidean distance,
## cut the tree into ten clusters and reconstruct the upper part of the
## tree from the cluster centers.
hc <- hclust(dist(USArrests)^2, "cen")
memb <- cutree(hc, k = 10)
cent <- NULL
for(k in 1:10){
  cent <- rbind(cent, colMeans(USArrests[memb == k, , drop = FALSE]))
}
hc1 <- hclust(dist(cent)^2, method = "cen", members = table(memb))
opar <- par(mfrow = c(1, 2))
plot(hc, labels = FALSE, hang = -1, main = "Original Tree")
plot(hc1, labels = FALSE, hang = -1, main = "Re-start from 10 clusters")
par(opar)

### Example 2: Straight-line distances among 10 US cities
## Compare the results of algorithms "ward.D" and "ward.D2"

mds2 <- -cmdscale(UScitiesD)
plot(mds2, type="n", axes=FALSE, ann=FALSE)
text(mds2, labels=rownames(mds2), xpd = NA)

hcity.D <- hclust(UScitiesD, "ward.D") # "wrong"
hcity.D2 <- hclust(UScitiesD, "ward.D2")
opar <- par(mfrow = c(1, 2))
plot(hcity.D, hang=-1)
plot(hcity.D2, hang=-1)
par(opar)
```

---

heatmap

---

*Draw a Heat Map*

---

**Description**

A heat map is a false color image (basically `image(t(x))`) with a dendrogram added to the left side and to the top. Typically, reordering of the rows and columns according to some set of values (row or column means) within the restrictions imposed by the dendrogram is carried out.

**Usage**

```
heatmap(x, Rowv = NULL, Colv = if(symm)"Rowv" else NULL,
        distfun = dist, hclustfun = hclust,
        reorderfun = function(d, w) reorder(d, w),
        add.expr, symm = FALSE, revC = identical(Colv, "Rowv"),
        scale = c("row", "column", "none"), na.rm = TRUE,
        margins = c(5, 5), ColSideColors, RowSideColors,
        cexRow = 0.2 + 1/log10(nr), cexCol = 0.2 + 1/log10(nc),
        labRow = NULL, labCol = NULL, main = NULL,
        xlab = NULL, ylab = NULL,
        keep.dendro = FALSE, verbose = getOption("verbose"), ...)
```

**Arguments**

|               |                                                                                                                                                                                                                                                                                                                                           |
|---------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| x             | numeric matrix of the values to be plotted.                                                                                                                                                                                                                                                                                               |
| Rowv          | determines if and how the <i>row</i> dendrogram should be computed and reordered. Either a <a href="#">dendrogram</a> or a vector of values used to reorder the row dendrogram or <a href="#">NA</a> to suppress any row dendrogram (and reordering) or by default, <a href="#">NULL</a> , see ‘Details’ below.                           |
| Colv          | determines if and how the <i>column</i> dendrogram should be reordered. Has the same options as the Rowv argument above and <i>additionally</i> when x is a square matrix, Colv = "Rowv" means that columns should be treated identically to the rows (and so if there is to be no row dendrogram there will not be a column one either). |
| distfun       | function used to compute the distance (dissimilarity) between both rows and columns. Defaults to <a href="#">dist</a> .                                                                                                                                                                                                                   |
| hclustfun     | function used to compute the hierarchical clustering when Rowv or Colv are not dendrograms. Defaults to <a href="#">hclust</a> . Should take as argument a result of distfun and return an object to which <a href="#">as.dendrogram</a> can be applied.                                                                                  |
| reorderfun    | function(d, w) of dendrogram and weights for reordering the row and column dendrograms. The default uses <a href="#">reorder.dendrogram</a> .                                                                                                                                                                                             |
| add.expr      | expression that will be evaluated after the call to image. Can be used to add components to the plot.                                                                                                                                                                                                                                     |
| symm          | logical indicating if x should be treated <b>symmetrically</b> ; can only be true when x is a square matrix.                                                                                                                                                                                                                              |
| revC          | logical indicating if the column order should be <b>reversed</b> for plotting, such that e.g., for the symmetric case, the symmetry axis is as usual.                                                                                                                                                                                     |
| scale         | character indicating if the values on the heatmap should be centered and scaled in either the row direction or the column direction, or none. The default is "row" if symm is false, and "none" otherwise. This scaling only affects the <i>colour</i> scale; it does not scale the original data. See the Examples.                      |
| na.rm         | logical indicating whether NA's should be removed.                                                                                                                                                                                                                                                                                        |
| margins       | numeric vector of length 2 containing the margins (see <a href="#">par</a> (mar = *)) for column and row names, respectively.                                                                                                                                                                                                             |
| ColSideColors | (optional) character vector of length ncol(x) containing the color names for a horizontal side bar that may be used to annotate the columns of x.                                                                                                                                                                                         |
| RowSideColors | (optional) character vector of length nrow(x) containing the color names for a vertical side bar that may be used to annotate the rows of x.                                                                                                                                                                                              |

|                               |                                                                                                                                                                  |
|-------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>cexRow, cexCol</code>   | positive numbers, used as <code>cex.axis</code> in for the row or column axis labeling. The defaults currently only use number of rows or columns, respectively. |
| <code>labRow, labCol</code>   | character vectors with row and column labels to use; these default to <code>rownames(x)</code> or <code>colnames(x)</code> , respectively.                       |
| <code>main, xlab, ylab</code> | main, x- and y-axis titles; defaults to none.                                                                                                                    |
| <code>keep.dendro</code>      | logical indicating if the dendrogram(s) should be kept as part of the result (when <code>Rowv</code> and/or <code>Colv</code> are not NA).                       |
| <code>verbose</code>          | logical indicating if information should be printed.                                                                                                             |
| <code>...</code>              | additional arguments passed on to <code>image</code> , e.g., <code>col</code> specifying the colors.                                                             |

### Details

If either `Rowv` or `Colv` are dendrograms they are honored (and not reordered). Otherwise, dendrograms are computed as `dd <- as.dendrogram(hclustfun(distfun(X)))` where `X` is either `x` or `t(x)`.

If either is a vector (of 'weights') then the appropriate dendrogram is reordered according to the supplied values subject to the constraints imposed by the dendrogram, by `reorder(dd, Rowv)`, in the row case. If either is missing, as by default, then the ordering of the corresponding dendrogram is by the mean value of the rows/columns, i.e., in the case of rows, `Rowv <- rowMeans(x, na.rm = na.rm)`. If either is `NA`, no reordering will be done for the corresponding side.

By default (`scale = "row"`) the rows are scaled to have mean zero and standard deviation one. There is some empirical evidence from genomic plotting that this is useful.

### Value

Invisibly, a list with components

|                     |                                                                                                         |
|---------------------|---------------------------------------------------------------------------------------------------------|
| <code>rowInd</code> | row index permutation vector as returned by <code>order.dendrogram</code> .                             |
| <code>colInd</code> | column index permutation vector.                                                                        |
| <code>Rowv</code>   | the row dendrogram; only if input <code>Rowv</code> was not NA and <code>keep.dendro</code> is true.    |
| <code>Colv</code>   | the column dendrogram; only if input <code>Colv</code> was not NA and <code>keep.dendro</code> is true. |

### Note

Unless `Rowv = NA` (or `Colv = NA`), the original rows and columns are reordered *in any case* to match the dendrogram, e.g., the rows by `order.dendrogram(Rowv)` where `Rowv` is the (possibly `reorder()`ed) row dendrogram.

`heatmap()` uses `layout` and draws the `image` in the lower right corner of a 2x2 layout. Consequently, it can **not** be used in a multi column/row layout, i.e., when `par(mfrow = *)` or `(mfcol = *)` has been called.

HoltWinters

*Holt-Winters Filtering*

## Description

Computes Holt-Winters Filtering of a given time series. Unknown parameters are determined by minimizing the squared prediction error.

## Usage

```
HoltWinters(x, alpha = NULL, beta = NULL, gamma = NULL,
            seasonal = c("additive", "multiplicative"),
            start.periods = 2, l.start = NULL, b.start = NULL,
            s.start = NULL,
            optim.start = c(alpha = 0.3, beta = 0.1, gamma = 0.1),
            optim.control = list())
```

## Arguments

|               |                                                                                                                                                                                                           |
|---------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| x             | An object of class <code>ts</code>                                                                                                                                                                        |
| alpha         | <i>alpha</i> parameter of Holt-Winters Filter.                                                                                                                                                            |
| beta          | <i>beta</i> parameter of Holt-Winters Filter. If set to <code>FALSE</code> , the function will do exponential smoothing.                                                                                  |
| gamma         | <i>gamma</i> parameter used for the seasonal component. If set to <code>FALSE</code> , a non-seasonal model is fitted.                                                                                    |
| seasonal      | Character string to select an "additive" (the default) or "multiplicative" seasonal model. The first few characters are sufficient. (Only takes effect if <i>gamma</i> is non-zero).                      |
| start.periods | Start periods used in the autodetection of start values. Must be at least 2.                                                                                                                              |
| l.start       | Start value for level ( $a[0]$ ).                                                                                                                                                                         |
| b.start       | Start value for trend ( $b[0]$ ).                                                                                                                                                                         |
| s.start       | Vector of start values for the seasonal component ( $s_1[0] \dots s_p[0]$ )                                                                                                                               |
| optim.start   | Vector with named components <i>alpha</i> , <i>beta</i> , and <i>gamma</i> containing the starting values for the optimizer. Only the values needed must be specified. Ignored in the one-parameter case. |
| optim.control | Optional list with additional control parameters passed to <i>optim</i> if this is used. Ignored in the one-parameter case.                                                                               |

## Details

The additive Holt-Winters prediction function (for time series with period length  $p$ ) is

$$\hat{Y}[t+h] = a[t] + hb[t] + s[t-p+1+(h-1) \bmod p],$$

where  $a[t]$ ,  $b[t]$  and  $s[t]$  are given by

$$a[t] = \alpha(Y[t] - s[t-p]) + (1-\alpha)(a[t-1] + b[t-1])$$

$$b[t] = \beta(a[t] - a[t - 1]) + (1 - \beta)b[t - 1]$$

$$s[t] = \gamma(Y[t] - a[t]) + (1 - \gamma)s[t - p]$$

The multiplicative Holt-Winters prediction function (for time series with period length  $p$ ) is

$$\hat{Y}[t + h] = (a[t] + hb[t]) \times s[t - p + 1 + (h - 1) \bmod p].$$

where  $a[t]$ ,  $b[t]$  and  $s[t]$  are given by

$$a[t] = \alpha(Y[t]/s[t - p]) + (1 - \alpha)(a[t - 1] + b[t - 1])$$

$$b[t] = \beta(a[t] - a[t - 1]) + (1 - \beta)b[t - 1]$$

$$s[t] = \gamma(Y[t]/a[t]) + (1 - \gamma)s[t - p]$$

The data in  $x$  are required to be non-zero for a multiplicative model, but it makes most sense if they are all positive.

The function tries to find the optimal values of  $\alpha$  and/or  $\beta$  and/or  $\gamma$  by minimizing the squared one-step prediction error if they are NULL (the default). `optimize` will be used for the single-parameter case, and `optim` otherwise.

For seasonal models, start values for  $a$ ,  $b$  and  $s$  are inferred by performing a simple decomposition in trend and seasonal component using moving averages (see function [decompose](#)) on the `start.periods` first periods (a simple linear regression on the trend component is used for starting level and trend). For level/trend-models (no seasonal component), start values for  $a$  and  $b$  are  $x[2]$  and  $x[2] - x[1]$ , respectively. For level-only models (ordinary exponential smoothing), the start value for  $a$  is  $x[1]$ .

## Value

An object of class "HoltWinters", a list with components:

|                           |                                                                                                                                                                                                             |
|---------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>fitted</code>       | A multiple time series with one column for the filtered series as well as for the level, trend and seasonal components, estimated contemporaneously (that is at time $t$ and not at the end of the series). |
| <code>x</code>            | The original series                                                                                                                                                                                         |
| <code>alpha</code>        | alpha used for filtering                                                                                                                                                                                    |
| <code>beta</code>         | beta used for filtering                                                                                                                                                                                     |
| <code>gamma</code>        | gamma used for filtering                                                                                                                                                                                    |
| <code>coefficients</code> | A vector with named components $a$ , $b$ , $s_1$ , $\dots$ , $s_p$ containing the estimated values for the level, trend and seasonal components                                                             |
| <code>seasonal</code>     | The specified seasonal parameter                                                                                                                                                                            |
| <code>SSE</code>          | The final sum of squared errors achieved in optimizing                                                                                                                                                      |
| <code>call</code>         | The call used                                                                                                                                                                                               |

Hypergeometric

---

*The Hypergeometric Distribution*

---

**Description**

Density, distribution function, quantile function and random generation for the hypergeometric distribution.

**Usage**

```
dhyper(x, m, n, k, log = FALSE)
phyper(q, m, n, k, lower.tail = TRUE, log.p = FALSE)
qhyper(p, m, n, k, lower.tail = TRUE, log.p = FALSE)
rhyper(nn, m, n, k)
```

**Arguments**

|                         |                                                                                                                                             |
|-------------------------|---------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x, q</code>       | vector of quantiles representing the number of white balls drawn without replacement from an urn which contains both black and white balls. |
| <code>m</code>          | the number of white balls in the urn.                                                                                                       |
| <code>n</code>          | the number of black balls in the urn.                                                                                                       |
| <code>k</code>          | the number of balls drawn from the urn, hence must be in $0, 1, \dots, m + n$ .                                                             |
| <code>p</code>          | probability, it must be between 0 and 1.                                                                                                    |
| <code>nn</code>         | number of observations. If <code>length(nn) &gt; 1</code> , the length is taken to be the number required.                                  |
| <code>log, log.p</code> | logical; if TRUE, probabilities p are given as $\log(p)$ .                                                                                  |
| <code>lower.tail</code> | logical; if TRUE (default), probabilities are $P[X \leq x]$ , otherwise, $P[X > x]$ .                                                       |

### Details

The hypergeometric distribution is used for sampling *without* replacement. The density of this distribution with parameters  $m$ ,  $n$  and  $k$  (named  $Np$ ,  $N - Np$ , and  $n$ , respectively in the reference below, where  $N := m + n$  is also used in other references) is given by

$$p(x) = \binom{m}{x} \binom{n}{k-x} / \binom{m+n}{k}$$

for  $x = 0, \dots, k$ .

Note that  $p(x)$  is non-zero only for  $\max(0, k - n) \leq x \leq \min(k, m)$ .

With  $p := m/(m + n)$  (hence  $Np = N \times p$  in the reference's notation), the first two moments are mean

$$E[X] = \mu = kp$$

and variance

$$\text{Var}(X) = kp(1-p) \frac{m+n-k}{m+n-1},$$

which shows the closeness to the  $\text{Binomial}(k, p)$  (where the hypergeometric has smaller variance unless  $k = 1$ ).

The quantile is defined as the smallest value  $x$  such that  $F(x) \geq p$ , where  $F$  is the distribution function.

In `rhyper()`, if one of  $m, n, k$  exceeds `.Machine$integer.max`, currently the equivalent of `qhyper(runif(nn), m, n, k)` is used which is comparably slow while instead a binomial approximation may be considerably more efficient.

### Value

`dhyper` gives the density, `phyper` gives the distribution function, `qhyper` gives the quantile function, and `rhyper` generates random deviates.

Invalid arguments will result in return value `NaN`, with a warning.

The length of the result is determined by `n` for `rhyper`, and is the maximum of the lengths of the numerical arguments for the other functions.

The numerical arguments other than `n` are recycled to the length of the result. Only the first elements of the logical arguments are used.

### Source

`dhyper` computes via binomial probabilities, using code contributed by Catherine Loader (see [dbinom](#)).

`phyper` is based on calculating `dhyper` and `phyper(...)/dhyper(...)` (as a summation), based on ideas of Ian Smith and Morten Welinder.

`qhyper` is based on inversion (of an earlier `phyper()` algorithm).

`rhyper` is based on a corrected version of

Kachitvichyanukul, V. and Schmeiser, B. (1985). Computer generation of hypergeometric random variates. *Journal of Statistical Computation and Simulation*, **22**, 127–145.

[Distributions](#) for other standard distributions.

**Examples**

```
m <- 10; n <- 7; k <- 8
x <- 0:(k+1)
rbind(phyper(x, m, n, k), dhyper(x, m, n, k))
all(phyper(x, m, n, k) == cumsum(dhyper(x, m, n, k))) # FALSE
## but errors are very small:
signif(phyper(x, m, n, k) - cumsum(dhyper(x, m, n, k)), digits = 3)

stopifnot(abs(phyper(x, m, n, k) - cumsum(dhyper(x, m, n, k))) < 5e-16)
```

---

identify.hclust

*Identify Clusters in a Dendrogram*

---

**Description**

identify.hclust reads the position of the graphics pointer when the (first) mouse button is pressed. It then cuts the tree at the vertical position of the pointer and highlights the cluster containing the horizontal position of the pointer. Optionally a function is applied to the index of data points contained in the cluster.

**Usage**

```
## S3 method for class 'hclust'
identify(x, FUN = NULL, N = 20, MAXCLUSTER = 20, DEV.FUN = NULL,
...)
```

**Arguments**

|            |                                                                                                                    |
|------------|--------------------------------------------------------------------------------------------------------------------|
| x          | an object of the type produced by hclust.                                                                          |
| FUN        | (optional) function to be applied to the index numbers of the data points in a cluster (see ‘Details’ below).      |
| N          | the maximum number of clusters to be identified.                                                                   |
| MAXCLUSTER | the maximum number of clusters that can be produced by a cut (limits the effective vertical range of the pointer). |
| DEV.FUN    | (optional) integer scalar. If specified, the corresponding graphics device is made active before FUN is applied.   |
| ...        | further arguments to FUN.                                                                                          |

**Details**

By default clusters can be identified using the mouse and an [invisible](#) list of indices of the respective data points is returned.

If FUN is not NULL, then the index vector of data points is passed to this function as first argument, see the examples below. The active graphics device for FUN can be specified using DEV.FUN.

The identification process is terminated by pressing any mouse button other than the first, see also [identify](#).

**Value**

Either a list of data point index vectors or a list of return values of FUN.

**See Also**

[hclust](#), [rect.hclust](#)

**Examples**

```
## Not run:
require(graphics)

hca <- hclust(dist(USArrests))
plot(hca)
(x <- identify(hca)) ## Terminate with 2nd mouse button !!

hci <- hclust(dist(iris[,1:4]))
plot(hci)
identify(hci, function(k) print(table(iris[k,5])))

# open a new device (one for dendrogram, one for bars):
dev.new() # << make that narrow (& small)
# and *beside* 1st one
nD <- dev.cur() # to be for the barplot
dev.set(dev.prev()) # old one for dendrogram
plot(hci)
## select subtrees in dendrogram and "see" the species distribution:
identify(hci, function(k) barplot(table(iris[k,5]), col = 2:4), DEV.FUN = nD)

## End(Not run)
```

---

influence.measures

*Regression Deletion Diagnostics*

---

**Description**

This suite of functions can be used to compute some of the regression (leave-one-out deletion) diagnostics for linear and generalized linear models discussed in Belsley, Kuh and Welsch (1980), Cook and Weisberg (1982), etc.

**Usage**

```
influence.measures(model, infl = influence(model))

rstandard(model, ...)
## S3 method for class 'lm'
rstandard(model, infl = lm.influence(model, do.coef = FALSE),
          sd = sqrt(deviance(model)/df.residual(model)),
          type = c("sd.1", "predictive"), ...)
## S3 method for class 'glm'
rstandard(model, infl = influence(model, do.coef = FALSE),
          type = c("deviance", "pearson"), ...)
```

```

rstudent(model, ...)
## S3 method for class 'lm'
rstudent(model, infl = lm.influence(model, do.coef = FALSE),
         res = infl$wt.res, ...)
## S3 method for class 'glm'
rstudent(model, infl = influence(model, do.coef = FALSE), ...)

dffits(model, infl = , res = )

dfbeta(model, ...)
## S3 method for class 'lm'
dfbeta(model, infl = lm.influence(model, do.coef = TRUE), ...)

dfbetas(model, ...)
## S3 method for class 'lm'
dfbetas(model, infl = lm.influence(model, do.coef = TRUE), ...)

covratio(model, infl = lm.influence(model, do.coef = FALSE),
         res = weighted.residuals(model))

cooks.distance(model, ...)
## S3 method for class 'lm'
cooks.distance(model, infl = lm.influence(model, do.coef = FALSE),
              res = weighted.residuals(model),
              sd = sqrt(deviance(model)/df.residual(model)),
              hat = infl$hat, ...)
## S3 method for class 'glm'
cooks.distance(model, infl = influence(model, do.coef = FALSE),
              res = infl$pear.res,
              dispersion = summary(model)$dispersion,
              hat = infl$hat, ...)

hatvalues(model, ...)
## S3 method for class 'lm'
hatvalues(model, infl = lm.influence(model, do.coef = FALSE), ...)

hat(x, intercept = TRUE)

```

### Arguments

|                         |                                                                                                                                                                                                     |
|-------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>model</code>      | an R object, typically returned by <code>lm</code> or <code>glm</code> .                                                                                                                            |
| <code>infl</code>       | influence structure as returned by <code>lm.influence</code> or <code>influence</code> (the latter only for the <code>glm</code> method of <code>rstudent</code> and <code>cooks.distance</code> ). |
| <code>res</code>        | (possibly weighted) residuals, with proper default.                                                                                                                                                 |
| <code>sd</code>         | standard deviation to use, see default.                                                                                                                                                             |
| <code>dispersion</code> | dispersion (for <code>glm</code> objects) to use, see default.                                                                                                                                      |
| <code>hat</code>        | hat values $H_{ii}$ , see default.                                                                                                                                                                  |
| <code>type</code>       | type of residuals for <code>rstandard</code> , with different options and meanings for <code>lm</code> and <code>glm</code> . Can be abbreviated.                                                   |
| <code>x</code>          | the $X$ or design matrix.                                                                                                                                                                           |

|           |                                                    |
|-----------|----------------------------------------------------|
| intercept | should an intercept column be prepended to x?      |
| ...       | further arguments passed to or from other methods. |

### Details

The primary high-level function is `influence.measures` which produces a class "infl" object tabular display showing the DFBETAs for each model variable, DFFITs, covariance ratios, Cook's distances and the diagonal elements of the hat matrix. Cases which are influential with respect to any of these measures are marked with an asterisk.

The functions `dfbetas`, `dffits`, `covratio` and `cooks.distance` provide direct access to the corresponding diagnostic quantities. Functions `rstandard` and `rstudent` give the standardized and Studentized residuals respectively. (These re-normalize the residuals to have unit variance, using an overall and leave-one-out measure of the error variance respectively.)

Note that for *multivariate* `lm()` models (of class "mlm"), these functions return 3d arrays instead of matrices, or matrices instead of vectors.

Values for generalized linear models are approximations, as described in Williams (1987) (except that Cook's distances are scaled as  $F$  rather than as chi-square values). The approximations can be poor when some cases have large influence.

The optional `infl`, `res` and `sd` arguments are there to encourage the use of these direct access functions, in situations where, e.g., the underlying basic influence measures (from `lm.influence` or the generic `influence`) are already available.

Note that cases with `weights == 0` are *dropped* from all these functions, but that if a linear model has been fitted with `na.action = na.exclude`, suitable values are filled in for the cases excluded during fitting.

For linear models, `rstandard(*, type = "predictive")` provides leave-one-out cross validation residuals, and the "PRESS" statistic (**P**REdictive **S**um of **S**quares, the same as the CV score) of model `model` is

```
PRESS <- sum(rstandard(model, type="pred")^2)
```

The function `hat()` exists mainly for S (version 2) compatibility; we recommend using `hatvalues()` instead.

### Note

For `hatvalues`, `dfbeta`, and `dfbetas`, the method for linear models also works for generalized linear models.

### Author(s)

Several R core team members and John Fox, originally in his 'car' package.

                    cooks.distance(glmI)))
```

integrate

*Integration of One-Dimensional Functions***Description**

Adaptive quadrature of functions of one variable over a finite or infinite interval.

**Usage**

```
integrate(f, lower, upper, ..., subdivisions = 100L,
          rel.tol = .Machine$double.eps^0.25, abs.tol = rel.tol,
          stop.on.error = TRUE, keep.xy = FALSE, aux = NULL)
```

**Arguments**

|                            |                                                                                                                                                         |
|----------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>f</code>             | an R function taking a numeric first argument and returning a numeric vector of the same length. Returning a non-finite element will generate an error. |
| <code>lower, upper</code>  | the limits of integration. Can be infinite.                                                                                                             |
| <code>...</code>           | additional arguments to be passed to <code>f</code> .                                                                                                   |
| <code>subdivisions</code>  | the maximum number of subintervals.                                                                                                                     |
| <code>rel.tol</code>       | relative accuracy requested.                                                                                                                            |
| <code>abs.tol</code>       | absolute accuracy requested.                                                                                                                            |
| <code>stop.on.error</code> | logical. If true (the default) an error stops the function. If false some errors will give a result with a warning in the message component.            |
| <code>keep.xy</code>       | unused. For compatibility with S.                                                                                                                       |
| <code>aux</code>           | unused. For compatibility with S.                                                                                                                       |

**Details**

Note that arguments after `...` must be matched exactly.

If one or both limits are infinite, the infinite range is mapped onto a finite interval.

For a finite interval, globally adaptive interval subdivision is used in connection with extrapolation by Wynn's Epsilon algorithm, with the basic step being Gauss-Kronrod quadrature.

`rel.tol` cannot be less than  $\max(50 \cdot \text{Machine\$double.eps}, 0.5e-28)$  if `abs.tol`  $\leq 0$ .

Note that the comments in the C source code in '`R/src/appl/integrate.c`' give more details, particularly about reasons for failure (internal error code `ier`  $\geq 1$ ).

In R versions  $\leq 3.2.x$ , the first entries of `lower` and `upper` were used whereas an error is signalled now if they are not of length one.

**Value**

A list of class "integrate" with components

|              |                                                                 |
|--------------|-----------------------------------------------------------------|
| value        | the final estimate of the integral.                             |
| abs.error    | estimate of the modulus of the absolute error.                  |
| subdivisions | the number of subintervals produced in the subdivision process. |
| message      | "OK" or a character string giving the error message.            |
| call         | the matched call.                                               |

**Note**

Like all numerical integration routines, these evaluate the function on a finite set of points. If the function is approximately constant (in particular, zero) over nearly all its range it is possible that the result and error estimate may be seriously wrong.

When integrating over infinite intervals do so explicitly, rather than just using a large number as the endpoint. This increases the chance of a correct answer – any function whose integral over an infinite interval is finite must be near zero for most of that interval.

For values at a finite set of points to be a fair reflection of the behaviour of the function elsewhere, the function needs to be well-behaved, for example differentiable except perhaps for a small number of jumps or integrable singularities.

`f` must accept a vector of inputs and produce a vector of function evaluations at those points. The [Vectorize](#) function may be helpful to convert `f` to this form.

**Source**

Based on QUADPACK routines `dqags` and `dqagi` by R. Piessens and E. deDoncker–Kapenga, available from Netlib.

|              |                                                                                                                                                              |
|--------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------|
| x.factor     | a factor whose levels will form the x axis.                                                                                                                  |
| trace.factor | another factor whose levels will form the traces.                                                                                                            |
| response     | a numeric variable giving the response.                                                                                                                      |
| fun          | the function to compute the summary. Should return a single real value.                                                                                      |
| type         | the type of plot (see <a href="#">plot.default</a> ): lines or points or both.                                                                               |
| legend       | logical. Should a legend be included?                                                                                                                        |
| trace.label  | overall label for the legend.                                                                                                                                |
| fixed        | logical. Should the legend be in the order of the levels of trace.factor (TRUE) or in the order of the traces at their right-hand ends (FALSE, the default)? |
| xlab, ylab   | the x and y label of the plot each with a sensible default.                                                                                                  |
| ylim         | numeric of length 2 giving the y limits for the plot.                                                                                                        |
| lty          | line type for the lines drawn, with sensible default.                                                                                                        |

|                 |                                                                                                                                                                       |
|-----------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| col             | the color to be used for plotting.                                                                                                                                    |
| pch             | a vector of plotting symbols or characters, with sensible default.                                                                                                    |
| xpd             | determines clipping behaviour for the <a href="#">legend</a> used, see <a href="#">par</a> (xpd). Per default, the legend is <i>not</i> clipped at the figure border. |
| leg.bg, leg.bty | arguments passed to <a href="#">legend</a> ().                                                                                                                        |
| xtick           | logical. Should tick marks be used on the x axis?                                                                                                                     |
| xaxt, axes, ... | graphics parameters to be passed to the plotting routines.                                                                                                            |

## Details

By default the levels of `x.factor` are plotted on the x axis in their given order, with extra space on the right for the legend (if specified). If `x.factor` is an ordered factor and the levels are numeric, these numeric values are used for the x axis.

The response and hence its summary can contain missing values. If so, the missing values and the line segments joining them are omitted from the plot (and this can be somewhat disconcerting).

The graphics parameters `xlab`, `ylab`, `ylim`, `lty`, `col` and `pch` are given suitable defaults (and `xlim` and `xaxs` are set and cannot be overridden). The defaults are to cycle through the line types, use the foreground colour, and to use the symbols 1:9, 0, and the small letters to plot the traces.

## Note

Some of the argument names and the precise behaviour are chosen for S-compatibility.

## Examples

```
require(graphics)

with(ToothGrowth, {
  interaction.plot(dose, supp, len, fixed = TRUE)
  dose <- ordered(dose)
  interaction.plot(dose, supp, len, fixed = TRUE,
                  col = 2:3, leg.bty = "o", xtick = TRUE)
  interaction.plot(dose, supp, len, fixed = TRUE, col = 2:3, type = "p")
})

with(OrchardSprays, {
  interaction.plot(treatment, rowpos, decrease)
  interaction.plot(rowpos, treatment, decrease, cex.axis = 0.8)
  ## order the rows by their mean effect
  rowpos <- factor(rowpos,
                  levels = sort.list(tapply(decrease, rowpos, mean)))
  interaction.plot(rowpos, treatment, decrease, col = 2:9, lty = 1)
})
```

---

|     |                                |
|-----|--------------------------------|
| IQR | <i>The Interquartile Range</i> |
|-----|--------------------------------|

---

**Description**

computes interquartile range of the x values.

**Usage**

```
IQR(x, na.rm = FALSE, type = 7)
```

**Arguments**

|       |                                                                                          |
|-------|------------------------------------------------------------------------------------------|
| x     | a numeric vector.                                                                        |
| na.rm | logical. Should missing values be removed?                                               |
| type  | an integer selecting one of the many quantile algorithms, see <a href="#">quantile</a> . |

**Details**

Note that this function computes the quartiles using the [quantile](#) function rather than following Tukey's recommendations, i.e.,  $IQR(x) = \text{quantile}(x, 3/4) - \text{quantile}(x, 1/4)$ .

For normally  $N(m, 1)$  distributed  $X$ , the expected value of  $IQR(X)$  is  $2 \cdot \text{qnorm}(3/4) = 1.3490$ , i.e., for a normal-consistent estimate of the standard deviation, use  $IQR(x) / 1.349$ .

```

---

|                |                                           |
|----------------|-------------------------------------------|
| is.empty.model | <i>Test if a Model's Formula is Empty</i> |
|----------------|-------------------------------------------|

---

**Description**

R's formula notation allows models with no intercept and no predictors. These require special handling internally. `is.empty.model()` checks whether an object describes an empty model.

**Usage**

```
is.empty.model(x)
```

**Arguments**

`x` A terms object or an object with a terms method.

**Value**

TRUE if the model is empty

**See Also**

[lm](#), [glm](#)

**Examples**

```
y <- rnorm(20)
is.empty.model(y ~ 0)
is.empty.model(y ~ -1)
is.empty.model(lm(y ~ 0))
```

---

isoreg

*Isotonic / Monotone Regression*

---

**Description**

Compute the isotonic (monotonically increasing nonparametric) least squares regression which is piecewise constant.

**Usage**

```
isoreg(x, y = NULL)
```

**Arguments**

`x, y` coordinate vectors of the regression points. Alternatively a single plotting structure can be specified: see [xy.coords](#). The y values, and even `sum(y)` must be finite, currently.

**Details**

The algorithm determines the convex minorant  $m(x)$  of the *cumulative* data (i.e., `cumsum(y)`) which is piecewise linear and the result is  $m'(x)$ , a step function with level changes at locations where the convex  $m(x)$  touches the cumulative data polygon and changes slope.

[as.stepfun\(\)](#) returns a [stepfun](#) object which can be more parsimonious.

**Value**

`isoreg()` returns an object of class `isoreg` which is basically a list with components

|                 |                                                               |
|-----------------|---------------------------------------------------------------|
| <code>x</code>  | original (constructed) abscissa values <code>x</code> .       |
| <code>y</code>  | corresponding y values.                                       |
| <code>yf</code> | fitted values corresponding to <i>ordered</i> x values.       |
| <code>yc</code> | cumulative y values corresponding to <i>ordered</i> x values. |

|        |                                                                                                        |
|--------|--------------------------------------------------------------------------------------------------------|
| iKnots | integer vector giving indices where the fitted curve jumps, i.e., where the convex minorant has kinks. |
| isOrd  | logical indicating if original x values were ordered increasingly already.                             |
| ord    | if(!isOrd): integer permutation <code>order(x)</code> of <i>original</i> x.                            |
| call   | the <code>call</code> to <code>isoreg()</code> used.                                                   |

### Note

The inputs can be long vectors, but iKnots will wrap around at  $2^{31}$ .

The code should be improved to accept *weights* additionally and solve the corresponding weighted least squares problem.

‘Patches are welcome!’

the plotting method `plot.isoreg` with more examples; `isoMDS()` from the **MASS** package internally uses isotonic regression.

### Examples

```
require(graphics)

(ir <- isoreg(c(1,0,4,3,3,5,4,2,0)))
plot(ir, plot.type = "row")

(ir3 <- isoreg(y3 <- c(1,0,4,3,3,5,4,2, 3))) # last "3", not "0"
(fi3 <- as.stepfun(ir3))
(ir4 <- isoreg(1:10, y4 <- c(5, 9, 1:2, 5:8, 3, 8)))
cat(sprintf("R^2 = %.2f\n",
            1 - sum(residuals(ir4)^2) / ((10-1)*var(y4))))

## If you are interested in the knots alone :
with(ir4, cbind(iKnots, yf[iKnots]))

## Example of unordered x[] with ties:
x <- sample((0:30)/8)
y <- exp(x)
x. <- round(x) # ties!
plot(m <- isoreg(x., y))
stopifnot(all.equal(with(m, yf[iKnots]),
                    as.vector(tapply(y, x., mean)))))
```

KalmanLike

*Kalman Filtering***Description**

Use Kalman Filtering to find the (Gaussian) log-likelihood, or for forecasting or smoothing.

**Usage**

```
KalmanLike(y, mod, nit = 0L, update = FALSE)
KalmanRun(y, mod, nit = 0L, update = FALSE)
KalmanSmooth(y, mod, nit = 0L)
KalmanForecast(n.ahead = 10L, mod, update = FALSE)

makeARIMA(phi, theta, Delta, kappa = 1e6,
           SSinit = c("Gardner1980", "Rossignol2011"),
           tol = .Machine$double.eps)
```

**Arguments**

|            |                                                                                                                                                                          |
|------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| y          | a univariate time series.                                                                                                                                                |
| mod        | a list describing the state-space model: see ‘Details’.                                                                                                                  |
| nit        | the time at which the initialization is computed. nit = 0L implies that the initialization is for a one-step prediction, so Pn should not be computed at the first step. |
| update     | if TRUE the update mod object will be returned as attribute "mod" of the result.                                                                                         |
| n.ahead    | the number of steps ahead for which prediction is required.                                                                                                              |
| phi, theta | numeric vectors of length $\geq 0$ giving AR and MA parameters.                                                                                                          |
| Delta      | vector of differencing coefficients, so an ARMA model is fitted to $y[t] - \text{Delta}[1]*y[t-1] - \dots$                                                               |
| kappa      | the prior variance (as a multiple of the innovations variance) for the past observations in a differenced model.                                                         |
| SSinit     | a string specifying the algorithm to compute the Pn part of the state-space initialization; see ‘Details’.                                                               |
| tol        | tolerance eventually passed to <code>solve.default</code> when SSinit = "Rossignol2011".                                                                                 |

**Details**

These functions work with a general univariate state-space model with state vector ‘a’, transitions ‘ $a \leftarrow T a + R e$ ’,  $e \sim \mathcal{N}(0, \kappa Q)$  and observation equation ‘ $y = Z' a + \eta$ ’, ( $\eta \equiv \text{eta}$ ),  $\eta \sim \mathcal{N}(0, \kappa h)$ . The likelihood is a profile likelihood after estimation of  $\kappa$ .

The model is specified as a list with at least components

T the transition matrix

Z the observation coefficients

h the observation variance

V 'RQR'

a the current state estimate

P the current estimate of the state uncertainty matrix  $Q$

Pn the estimate at time  $t - 1$  of the state uncertainty matrix  $Q$  (not updated by KalmanForecast).

KalmanSmooth is the workhorse function for [tsSmooth](#).

makeARIMA constructs the state-space model for an ARIMA model, see also [arima](#).

The state-space initialization has used Gardner et al.'s method (`SSinit = "Gardner1980"`), as only method for years. However, that suffers sometimes from deficiencies when close to non-stationarity. For this reason, it may be replaced as default in the future and only kept for reproducibility reasons. Explicit specification of `SSinit` is therefore recommended, notably also in [arima\(\)](#). The "Rossignol2011" method has been proposed and partly documented by Raphael Rossignol, Univ. Grenoble, on 2011-09-20 (see [PR#14682](#), below), and later been ported to C by Matvey V. Kornilov. It computes the covariance matrix of  $(X_{t-1}, \dots, X_{t-p}, Z_t, \dots, Z_{t-q})$  by the method of difference equations (page 93 of Brockwell and Davis (1991)), apparently suggested by a referee of Gardner et al. (see p.314 of their paper).

## Value

For `KalmanLike`, a list with components `Lik` (the log-likelihood less some constants) and `s2`, the estimate of  $\kappa$ .

For `KalmanRun`, a list with components `values`, a vector of length 2 giving the output of `KalmanLike`, `resid` (the residuals) and `states`, the contemporaneous state estimates, a matrix with one row for each observation time.

For `KalmanSmooth`, a list with two components. Component `smooth` is a  $n$  by  $p$  matrix of state estimates based on all the observations, with one row for each time. Component `var` is a  $n$  by  $p$  by  $p$  array of variance matrices.

For `KalmanForecast`, a list with components `pred`, the predictions, and `var`, the unscaled variances of the prediction errors (to be multiplied by `s2`).

For `makeARIMA`, a model list including components for its arguments.

## Warning

These functions are designed to be called from other functions which check the validity of the arguments passed, so very little checking is done.

  mod <- attr(pr, "mod")
}
```

kernapply

*Apply Smoothing Kernel***Description**

kernapply computes the convolution between an input sequence and a specific kernel.

**Usage**

```
kernapply(x, ...)

## Default S3 method:
kernapply(x, k, circular = FALSE, ...)
## S3 method for class 'ts'
kernapply(x, k, circular = FALSE, ...)
## S3 method for class 'vector'
kernapply(x, k, circular = FALSE, ...)

## S3 method for class 'tskernel'
kernapply(x, k, ...)
```

**Arguments**

|          |                                                                                                        |
|----------|--------------------------------------------------------------------------------------------------------|
| x        | an input vector, matrix, time series or kernel to be smoothed.                                         |
| k        | smoothing "tskernel" object.                                                                           |
| circular | a logical indicating whether the input sequence to be smoothed is treated as circular, i.e., periodic. |
| ...      | arguments passed to or from other methods.                                                             |

**Value**

A smoothed version of the input sequence.

**Note**

This uses `fft` to perform the convolution, so is fastest when `NROW(x)` is a power of 2 or some other highly composite integer.

```

---

kernel

*Smoothing Kernel Objects*

---

**Description**

The "tskernel" class is designed to represent discrete symmetric normalized smoothing kernels. These kernels can be used to smooth vectors, matrices, or time series objects.

There are `print`, `plot` and `[]` methods for these kernel objects.

**Usage**

```
kernel(coef, m = 2, r, name)

df.kernel(k)
bandwidth.kernel(k)
is.tskernel(k)

## S3 method for class 'tskernel'
plot(x, type = "h", xlab = "k", ylab = "W[k]",
     main = attr(x,"name"), ...)
```

**Arguments**

|                                          |                                                                                                                                                                                                                                                                                                  |
|------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>coef</code>                        | the upper half of the smoothing kernel coefficients (including coefficient zero) <i>or</i> the name of a kernel (currently "daniell", "dirichlet", "fejer" or "modified.daniell").                                                                                                               |
| <code>m</code>                           | the kernel dimension(s) if <code>coef</code> is a name. When <code>m</code> has length larger than one, it means the convolution of kernels of dimension <code>m[j]</code> , for <code>j</code> in <code>1:length(m)</code> . Currently this is supported only for the named "*daniell" kernels. |
| <code>name</code>                        | the name the kernel will be called.                                                                                                                                                                                                                                                              |
| <code>r</code>                           | the kernel order for a Dirichlet or Fejer kernel.                                                                                                                                                                                                                                                |
| <code>k, x</code>                        | a "tskernel" object.                                                                                                                                                                                                                                                                             |
| <code>type, xlab, ylab, main, ...</code> | arguments passed to <code>plot.default</code> .                                                                                                                                                                                                                                                  |

## Details

`kernel` is used to construct a general kernel or named specific kernels. The modified Daniell kernel halves the end coefficients.

The `[]` method allows natural indexing of kernel objects with indices in  $(-m) : m$ . The normalization is such that for `k <- kernel(*)`, `sum(k[-k$m : k$m])` is one.

`df.kernel` returns the ‘equivalent degrees of freedom’ of a smoothing kernel as defined in Brockwell and Davis (1991), page 362, and `bandwidth.kernel` returns the equivalent bandwidth as defined in Bloomfield (1976), p. 201, with a continuity correction.

## Value

`kernel()` returns an object of class `"tskernel"` which is basically a list with the two components `coef` and the kernel dimension `m`. An additional attribute is `"name"`.

kmeans

*K-Means Clustering***Description**

Perform k-means clustering on a data matrix.

**Usage**

```
kmeans(x, centers, iter.max = 10, nstart = 1,
       algorithm = c("Hartigan-Wong", "Lloyd", "Forgy",
                     "MacQueen"), trace = FALSE)
## S3 method for class 'kmeans'
fitted(object, method = c("centers", "classes"), ...)
```

**Arguments**

|                        |                                                                                                                                                                                                                                      |
|------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>         | numeric matrix of data, or an object that can be coerced to such a matrix (such as a numeric vector or a data frame with all numeric columns).                                                                                       |
| <code>centers</code>   | either the number of clusters, say $k$ , or a set of initial (distinct) cluster centres. If a number, a random set of (distinct) rows in <code>x</code> is chosen as the initial centres.                                            |
| <code>iter.max</code>  | the maximum number of iterations allowed.                                                                                                                                                                                            |
| <code>nstart</code>    | if <code>centers</code> is a number, how many random sets should be chosen?                                                                                                                                                          |
| <code>algorithm</code> | character: may be abbreviated. Note that "Lloyd" and "Forgy" are alternative names for one algorithm.                                                                                                                                |
| <code>object</code>    | an R object of class "kmeans", typically the result <code>ob</code> of <code>ob &lt;- kmeans(...)</code> .                                                                                                                           |
| <code>method</code>    | character: may be abbreviated. "centers" causes <code>fitted</code> to return cluster centers (one for each input point) and "classes" causes <code>fitted</code> to return a vector of class assignments.                           |
| <code>trace</code>     | logical or integer number, currently only used in the default method ("Hartigan-Wong"): if positive (or true), tracing information on the progress of the algorithm is produced. Higher values may produce more tracing information. |
| <code>...</code>       | not used.                                                                                                                                                                                                                            |

**Details**

The data given by `x` are clustered by the  $k$ -means method, which aims to partition the points into  $k$  groups such that the sum of squares from points to the assigned cluster centres is minimized. At the minimum, all cluster centres are at the mean of their Voronoi sets (the set of data points which are nearest to the cluster centre).

The algorithm of Hartigan and Wong (1979) is used by default. Note that some authors use  $k$ -means to refer to a specific algorithm rather than the general method: most commonly the algorithm given by MacQueen (1967) but sometimes that given by Lloyd (1957) and Forgy (1965). The Hartigan-Wong algorithm generally does a better job than either of those, but trying several random starts (`nstart > 1`) is often recommended. In rare cases, when some of the points (rows of `x`) are extremely close, the algorithm may not converge in the "Quick-Transfer" stage, signalling a warning (and returning `ifault = 4`). Slight rounding of the data may be advisable in that case.

For ease of programmatic exploration,  $k = 1$  is allowed, notably returning the center and withinss. Except for the Lloyd–Forgy method,  $k$  clusters will always be returned if a number is specified. If an initial matrix of centres is supplied, it is possible that no point will be closest to one or more centres, which is currently an error for the Hartigan–Wong method.

### Value

kmeans returns an object of class "kmeans" which has a print and a fitted method. It is a list with at least the following components:

|              |                                                                                          |
|--------------|------------------------------------------------------------------------------------------|
| cluster      | A vector of integers (from 1:k) indicating the cluster to which each point is allocated. |
| centers      | A matrix of cluster centres.                                                             |
| totss        | The total sum of squares.                                                                |
| withinss     | Vector of within-cluster sum of squares, one component per cluster.                      |
| tot.withinss | Total within-cluster sum of squares, i.e. sum(withinss).                                 |
| betweenss    | The between-cluster sum of squares, i.e. totss-tot.withinss.                             |
| size         | The number of points in each cluster.                                                    |
| iter         | The number of (outer) iterations.                                                        |
| ifault       | integer: indicator of a possible algorithm problem – for experts.                        |

### Note

The clusters are numbered in the returned object, but they are a *set* and no ordering is implied. (Their apparent ordering may differ by platform.)

### Examples

```
require(graphics)

# a 2-dimensional example
x <- rbind(matrix(rnorm(100, sd = 0.3), ncol = 2),
           matrix(rnorm(100, mean = 1, sd = 0.3), ncol = 2))
colnames(x) <- c("x", "y")
(cl <- kmeans(x, 2))
plot(x, col = cl$cluster)
points(cl$centers, col = 1:2, pch = 8, cex = 2)

# sum of squares
```

```

ss <- function(x) sum(scale(x, scale = FALSE)^2)

## cluster centers "fitted" to each obs.:
fitted.x <- fitted(cl); head(fitted.x)
resid.x <- x - fitted(cl)

## Equalities : -----
cbind(cl[c("betweenss", "tot.withinss", "totss")], # the same two columns
      c(ss(fitted.x), ss(resid.x), ss(x)))
stopifnot(all.equal(cl$ totss, ss(x)),
          all.equal(cl$ tot.withinss, ss(resid.x)),
          ## these three are the same:
          all.equal(cl$ betweenss, ss(fitted.x)),
          all.equal(cl$ betweenss, cl$totss - cl$tot.withinss),
          ## and hence also
          all.equal(ss(x), ss(fitted.x) + ss(resid.x))
          )

kmeans(x,1)$withinss # trivial one-cluster, (its W.SS == ss(x))

## random starts do help here with too many clusters
## (and are often recommended anyway!):
## The ordering of the clusters may be platform-dependent.

(cl <- kmeans(x, 5, nstart = 25))

plot(x, col = cl$cluster)
points(cl$centers, col = 1:5, pch = 8)

```

---

kruskal.test

*Kruskal-Wallis Rank Sum Test*

---

## Description

Performs a Kruskal-Wallis rank sum test.

## Usage

```

kruskal.test(x, ...)

## Default S3 method:
kruskal.test(x, g, ...)

## S3 method for class 'formula'
kruskal.test(formula, data, subset, na.action, ...)
```

## Arguments

|   |                                                                                                                                     |
|---|-------------------------------------------------------------------------------------------------------------------------------------|
| x | a numeric vector of data values, or a list of numeric data vectors. Non-numeric elements of a list will be coerced, with a warning. |
| g | a vector or factor object giving the group for the corresponding elements of x. Ignored with a warning if x is a list.              |

|           |                                                                                                                                                                                                                            |
|-----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| formula   | a formula of the form <code>response ~ group</code> where <code>response</code> gives the data values and <code>group</code> a vector or factor of the corresponding groups.                                               |
| data      | an optional matrix or data frame (or similar: see <a href="#">model.frame</a> ) containing the variables in the formula <code>formula</code> . By default the variables are taken from <code>environment(formula)</code> . |
| subset    | an optional vector specifying a subset of observations to be used.                                                                                                                                                         |
| na.action | a function which indicates what should happen when the data contain NAs. Defaults to <code>getOption("na.action")</code> .                                                                                                 |
| ...       | further arguments to be passed to or from methods.                                                                                                                                                                         |

### Details

`kruskal.test` performs a Kruskal-Wallis rank sum test of the null that the location parameters of the distribution of `x` are the same in each group (sample). The alternative is that they differ in at least one.

If `x` is a list, its elements are taken as the samples to be compared, and hence have to be numeric data vectors. In this case, `g` is ignored, and one can simply use `kruskal.test(x)` to perform the test. If the samples are not yet contained in a list, use `kruskal.test(list(x, ...))`.

Otherwise, `x` must be a numeric data vector, and `g` must be a vector or factor object of the same length as `x` giving the group for the corresponding elements of `x`.

### Value

A list with class `"htest"` containing the following components:

|           |                                                                                           |
|-----------|-------------------------------------------------------------------------------------------|
| statistic | the Kruskal-Wallis rank sum statistic.                                                    |
| parameter | the degrees of freedom of the approximate chi-squared distribution of the test statistic. |
| p.value   | the p-value of the test.                                                                  |
| method    | the character string <code>"Kruskal-Wallis rank sum test"</code> .                        |
| data.name | a character string giving the names of the data.                                          |

ks.test

*Kolmogorov-Smirnov Tests*

---

## Description

Perform a one- or two-sample Kolmogorov-Smirnov test.

## Usage

```
ks.test(x, ...)
## Default S3 method:
ks.test(x, y, ...,
        alternative = c("two.sided", "less", "greater"),
        exact = NULL, simulate.p.value = FALSE, B = 2000)
## S3 method for class 'formula'
ks.test(formula, data, subset, na.action, ...)
```

## Arguments

|             |                                                                                                                                                                                                                                                                |
|-------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| x           | a numeric vector of data values.                                                                                                                                                                                                                               |
| y           | either a numeric vector of data values, or a character string naming a cumulative distribution function or an actual cumulative distribution function such as <code>pnorm</code> . Only continuous CDFs are valid.                                             |
| ...         | for the default method, parameters of the distribution specified (as a character string) by y. Otherwise, further arguments to be passed to or from methods.                                                                                                   |
| alternative | indicates the alternative hypothesis and must be one of "two.sided" (default), "less", or "greater". You can specify just the initial letter of the value, but the argument name must be given in full. See 'Details' for the meanings of the possible values. |

|                               |                                                                                                                                                                                                                                                         |
|-------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>exact</code>            | NULL or a logical indicating whether an exact p-value should be computed. See ‘Details’ for the meaning of NULL.                                                                                                                                        |
| <code>simulate.p.value</code> | a logical indicating whether to compute p-values by Monte Carlo simulation. (Ignored for the one-sample test.)                                                                                                                                          |
| <code>B</code>                | an integer specifying the number of replicates used in the Monte Carlo test.                                                                                                                                                                            |
| <code>formula</code>          | a formula of the form <code>lhs ~ rhs</code> where <code>lhs</code> is a numeric variable giving the data values and <code>rhs</code> either 1 for a one-sample test or a factor with two levels giving the corresponding groups for a two-sample test. |
| <code>data</code>             | an optional matrix or data frame (or similar: see <code>model.frame</code> ) containing the variables in the formula <code>formula</code> . By default the variables are taken from <code>environment(formula)</code> .                                 |
| <code>subset</code>           | an optional vector specifying a subset of observations to be used.                                                                                                                                                                                      |
| <code>na.action</code>        | a function which indicates what should happen when the data contain NAs. Defaults to <code>getOption("na.action")</code> .                                                                                                                              |

## Details

If `y` is numeric, a two-sample (Smirnov) test of the null hypothesis that `x` and `y` were drawn from the same distribution is performed.

Alternatively, `y` can be a character string naming a continuous (cumulative) distribution function, or such a function. In this case, a one-sample (Kolmogorov) test is carried out of the null that the distribution function which generated `x` is distribution `y` with parameters specified by `...`. The presence of ties always generates a warning in the one-sample case, as continuous distributions do not generate them. If the ties arose from rounding the tests may be approximately valid, but even modest amounts of rounding can have a significant effect on the calculated statistic.

Missing values are silently omitted from `x` and (in the two-sample case) `y`.

The possible values `"two.sided"`, `"less"` and `"greater"` of `alternative` specify the null hypothesis that the true cumulative distribution function (CDF) of `x` is equal to, not less than or not greater than the hypothesized CDF (one-sample case) or the CDF of `y` (two-sample case), respectively. The test compares the CDFs taking their maximal difference as test statistic, with the statistic in the `"greater"` alternative being  $D^+ = \max_u [F_x(u) - F_y(u)]$ . Thus in the two-sample case `alternative = "greater"` includes distributions for which `x` is stochastically *smaller* than `y` (the CDF of `x` lies above and hence to the left of that for `y`), in contrast to `t.test` or `wilcox.test`.

Exact p-values are not available for the one-sample case in the presence of ties. If `exact = NULL` (the default), an exact p-value is computed if the sample size is less than 100 in the one-sample case *and there are no ties*, and if the product of the sample sizes is less than 10000 in the two-sample case, with or without ties (using the algorithm described in Schröer and Trenkler (1995)). Otherwise, the p-value is computed via Monte Carlo simulation in the two-sample case if `simulate.p.value` is TRUE, or else asymptotic distributions are used whose approximations may be inaccurate in small samples. In the one-sample two-sided case, exact p-values are obtained as described in Marsaglia, Tsang & Wang (2003) (but not using the optional approximation in the right tail, so this can be slow for small p-values). The formula of Birnbaum & Tingey (1951) is used for the one-sample one-sided case.

If a one-sample test is used, the parameters specified in `...` must be pre-specified and not estimated from the data. There is some more refined distribution theory for the KS test with estimated parameters (see Durbin, 1973), but that is not implemented in `ks.test`.

**Value**

A list inheriting from classes "ks.test" and "htest" containing the following components:

|             |                                                                |
|-------------|----------------------------------------------------------------|
| statistic   | the value of the test statistic.                               |
| p.value     | the p-value of the test.                                       |
| alternative | a character string describing the alternative hypothesis.      |
| method      | a character string indicating what type of test was performed. |
| data.name   | a character string giving the name(s) of the data.             |

**Source**

The two-sided one-sample distribution comes *via* Marsaglia, Tsang and Wang (2003).

Exact distributions for the two-sample (Smirnov) test are computed by the algorithm proposed by Schröder (1991) and Schröder & Trenkler (1995) using numerical improvements along the lines of Viehmann (2021).

        subset = Month %in% c(5, 8))

```

ksmooth

*Kernel Regression Smoother***Description**

The Nadaraya–Watson kernel regression estimate.

**Usage**

```

ksmooth(x, y, kernel = c("box", "normal"), bandwidth = 0.5,
        range.x = range(x),
        n.points = max(100L, length(x)), x.points)

```

**Arguments**

|           |                                                                                                                                            |
|-----------|--------------------------------------------------------------------------------------------------------------------------------------------|
| x         | input x values. <a href="#">Long vectors</a> are supported.                                                                                |
| y         | input y values. Long vectors are supported.                                                                                                |
| kernel    | the kernel to be used. Can be abbreviated.                                                                                                 |
| bandwidth | the bandwidth. The kernels are scaled so that their quartiles (viewed as probability densities) are at $\pm 0.25 \cdot \text{bandwidth}$ . |
| range.x   | the range of points to be covered in the output.                                                                                           |
| n.points  | the number of points at which to evaluate the fit.                                                                                         |
| x.points  | points at which to evaluate the smoothed fit. If missing, n.points are chosen uniformly to cover range.x. Long vectors are supported.      |

**Value**

A list with components

|   |                                                                                      |
|---|--------------------------------------------------------------------------------------|
| x | values at which the smoothed fit is evaluated. Guaranteed to be in increasing order. |
| y | fitted values corresponding to x.                                                    |

**Note**

This function was implemented for compatibility with S, although it is nowhere near as slow as the S function. Better kernel smoothers are available in other packages such as **KernSmooth**.

**Examples**

```
require(graphics)

with(cars, {
  plot(speed, dist)
  lines(ksmooth(speed, dist, "normal", bandwidth = 2), col = 2)
  lines(ksmooth(speed, dist, "normal", bandwidth = 5), col = 3)
})
```

lag

*Lag a Time Series***Description**

Compute a lagged version of a time series, shifting the time base back by a given number of observations.

lag is a generic function; this page documents its default method.

**Usage**

```
lag(x, ...)

## Default S3 method:
lag(x, k = 1, ...)
```

**Arguments**

|     |                                                              |
|-----|--------------------------------------------------------------|
| x   | A vector or matrix or univariate or multivariate time series |
| k   | The number of lags (in units of observations).               |
| ... | further arguments to be passed to or from methods.           |

**Details**

Vector or matrix arguments x are given a tsp attribute *via* [hasTsp](#).

**Value**

A time series object with the same class as x.

**Note**

Note the sign of k: a series lagged by a positive k starts *earlier*.

**References**

Becker, R. A., Chambers, J. M. and Wilks, A. R. (1988) *The New S Language*. Wadsworth & Brooks/Cole.

**See Also**[diff](#), [deltat](#)**Examples**

```
lag(ldeaths, 12) # starts one year earlier
```

lag.plot

*Time Series Lag Plots***Description**

Plot time series against lagged versions of themselves. Helps visualizing ‘auto-dependence’ even when auto-correlations vanish.

**Usage**

```
lag.plot(x, lags = 1, layout = NULL, set.lags = 1:lags,
        main = NULL, asp = 1,
        diag = TRUE, diag.col = "gray", type = "p", oma = NULL,
        ask = NULL, do.lines = (n <= 150), labels = do.lines,
        ...)
```

**Arguments**

|          |                                                                                                                                                                                                                                                                                                                                                |
|----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| x        | time-series (univariate or multivariate)                                                                                                                                                                                                                                                                                                       |
| lags     | number of lag plots desired, see argument <code>set.lags</code> .                                                                                                                                                                                                                                                                              |
| layout   | the layout of multiple plots, basically the <code>mfrow</code> <a href="#">par()</a> argument. The default uses about a square layout (see <a href="#">n2mfrow</a> ) such that all plots are on one page.                                                                                                                                      |
| set.lags | vector of positive integers allowing specification of the set of lags used; defaults to <code>1:lags</code> .                                                                                                                                                                                                                                  |
| main     | character with a main header title to be done on the top of each page.                                                                                                                                                                                                                                                                         |
| asp      | Aspect ratio to be fixed, see <a href="#">plot.default</a> .                                                                                                                                                                                                                                                                                   |
| diag     | logical indicating if the x=y diagonal should be drawn.                                                                                                                                                                                                                                                                                        |
| diag.col | color to be used for the diagonal if <code>(diag)</code> .                                                                                                                                                                                                                                                                                     |
| type     | plot type to be used, but see <a href="#">plot.ts</a> about its restricted meaning.                                                                                                                                                                                                                                                            |
| oma      | outer margins, see <a href="#">par</a> .                                                                                                                                                                                                                                                                                                       |
| ask      | logical or NULL; if true, the user is asked to confirm before a new page is started.                                                                                                                                                                                                                                                           |
| do.lines | logical indicating if lines should be drawn.                                                                                                                                                                                                                                                                                                   |
| labels   | logical indicating if labels should be used.                                                                                                                                                                                                                                                                                                   |
| ...      | Further arguments to <a href="#">plot.ts</a> . Several graphical parameters are set in this function and so cannot be changed: these include <code>xlab</code> , <code>ylab</code> , <code>mgp</code> , <code>col.lab</code> and <code>font.lab</code> : this also applies to the arguments <code>xy.labels</code> and <code>xy.lines</code> . |

### Details

If just one plot is produced, this is a conventional plot. If more than one plot is to be produced, `par(mfrow)` and several other graphics parameters will be set, so it is not (easily) possible to mix such lag plots with other plots on the same page.

If `ask = NULL`, `par(ask = TRUE)` will be called if more than one page of plots is to be produced and the device is interactive.

### Note

It is more flexible and has different default behaviour than the S version. We use `main =` instead of `head =` for internal consistency.

### Author(s)

Martin Maechler

### See Also

[plot.ts](#) which is the basic work horse.

### Examples

```
require(graphics)

lag.plot(nhtemp, 8, diag.col = "forest green")
lag.plot(nhtemp, 5, main = "Average Temperatures in New Haven")
## ask defaults to TRUE when we have more than one page:
lag.plot(nhtemp, 6, layout = c(2,1), asp = NA,
        main = "New Haven Temperatures", col.main = "blue")

## Multivariate (but non-stationary! ...)
lag.plot(freeny.x, lags = 3)

## no lines for long series :
lag.plot(sqrt(sunspots), set.lags = c(1:4, 9:12), pch = ".", col = "gold")
```

---

line

*Robust Line Fitting*

---

### Description

Fit a line robustly as recommended in *Exploratory Data Analysis*.

Currently by default (`iter = 1`) the initial median-median line is *not* iterated (as opposed to Tukey's "resistant line" in the references).

### Usage

```
line(x, y, iter = 1)
```

## Arguments

`x, y` the arguments can be any way of specifying x-y pairs. See [xy.coords](#).  
`iter` positive integer specifying the number of “polishing” iterations. Note that this was hard coded to 1 in R versions before 3.5.0, and more importantly that such simple iterations may not converge, see Siegel’s 9-point example.

## Details

Cases with missing values are omitted.

Contrary to the references where the data is split in three (almost) equally sized groups with symmetric sizes depending on  $n$  and  $n \% 3$  and computes medians inside each group, the `line()` code splits into three groups using all observations with  $x[.] \leq q1$  and  $x[.] \geq q2$ , where  $q1$ ,  $q2$  are (a kind of) quantiles for probabilities  $p = 1/3$  and  $p = 2/3$  of the form  $(x[j1] + x[j2])/2$  where  $j1 = \text{floor}(p*(n-1))$  and  $j2 = \text{ceiling}(p*(n-1))$ ,  $n = \text{length}(x)$ .

Long vectors are not supported yet.

## Value

An object of class “`tukeyline`”.

Methods are available for the generic functions `coef`, `residuals`, `fitted`, and `print`.

[lm](#).

There are alternatives for robust linear regression more robust and more (statistically) efficient, see [r1m\(\)](#) from **MASS**, or [lmrob\(\)](#) from **robustbase**.

## Examples

```
require(graphics)

plot(cars)
(z <- line(cars))
abline(coef(z))
## Tukey-Anscombe Plot :
plot(residuals(z) ~ fitted(z), main = deparse(z$call))

## Andrew Siegel's pathological 9-point data, y-values multiplied by 3:
d.AS <- data.frame(x = c(-4:3, 12), y = 3*c(rep(0,6), -5, 5, 1))
cAS <- with(d.AS, t(sapply(1:10,
```

```

      function(it) line(x,y, iter=it)$coefficients)))
dimnames(cAS) <- list(paste("it =", format(1:10)), c("intercept", "slope"))
cAS
## iterations started to oscillate, repeating iteration 7,8 indefinitely

```

listof

*A Class for Lists of (Parts of) Model Fits***Description**

Class "listof" is used by [aov](#) and the "lm" method of [alias](#) for lists of model fits or parts thereof. It is simply a list with an assigned class to control the way methods, especially printing, act on it. It has a [coef](#) method in this package (which returns an object of this class), and `[]` and `print` methods in package **base**.

lm

*Fitting Linear Models***Description**

lm is used to fit linear models, including multivariate ones. It can be used to carry out regression, single stratum analysis of variance and analysis of covariance (although [aov](#) may provide a more convenient interface for these).

**Usage**

```

lm(formula, data, subset, weights, na.action,
   method = "qr", model = TRUE, x = FALSE, y = FALSE, qr = TRUE,
   singular.ok = TRUE, contrasts = NULL, offset, ...)

## S3 method for class 'lm'
print(x, digits = max(3L, getOption("digits") - 3L), ...)

```

**Arguments**

|         |                                                                                                                                                                                                                                                                                       |
|---------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| formula | an object of class " <a href="#">formula</a> " (or one that can be coerced to that class): a symbolic description of the model to be fitted. The details of model specification are given under 'Details'.                                                                            |
| data    | an optional data frame, list or environment (or object coercible by <a href="#">as.data.frame</a> to a data frame) containing the variables in the model. If not found in data, the variables are taken from environment(formula), typically the environment from which lm is called. |
| subset  | an optional vector specifying a subset of observations to be used in the fitting process. (See additional details about how this argument interacts with data-dependent bases in the 'Details' section of the <a href="#">model.frame</a> documentation.)                             |
| weights | an optional vector of weights to be used in the fitting process. Should be NULL or a numeric vector. If non-NULL, weighted least squares is used with weights weights (that is, minimizing $\sum(w \cdot e^2)$ ); otherwise ordinary least squares is used. See also 'Details'.       |

|                 |                                                                                                                                                                                                                                                                                                                                                                                                                |
|-----------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| na.action       | a function which indicates what should happen when the data contain NAs. The default is set by the na.action setting of <code>options</code> , and is <code>na.fail</code> if that is unset. The ‘factory-fresh’ default is <code>na.omit</code> . Another possible value is <code>NULL</code> , no action. Value <code>na.exclude</code> can be useful.                                                       |
| method          | the method to be used; for fitting, currently only <code>method = "qr"</code> is supported; <code>method = "model.frame"</code> returns the model frame (the same as with <code>model = TRUE</code> , see below).                                                                                                                                                                                              |
| model, x, y, qr | logicals. If <code>TRUE</code> the corresponding components of the fit (the model frame, the model matrix, the response, the QR decomposition) are returned.                                                                                                                                                                                                                                                   |
| singular.ok     | logical. If <code>FALSE</code> (the default in <code>S</code> but not in <code>R</code> ) a singular fit is an error.                                                                                                                                                                                                                                                                                          |
| contrasts       | an optional list. See the <code>contrasts.arg</code> of <code>model.matrix.default</code> .                                                                                                                                                                                                                                                                                                                    |
| offset          | this can be used to specify an <i>a priori</i> known component to be included in the linear predictor during fitting. This should be <code>NULL</code> or a numeric vector or matrix of extents matching those of the response. One or more <code>offset</code> terms can be included in the formula instead or as well, and if more than one are specified their sum is used. See <code>model.offset</code> . |
| ...             | For <code>lm()</code> : additional arguments to be passed to the low level regression fitting functions (see below).                                                                                                                                                                                                                                                                                           |
| digits          | the number of <i>significant</i> digits to be passed to <code>format(coef(x), .)</code> when <code>print()</code> ing.                                                                                                                                                                                                                                                                                         |

## Details

Models for `lm` are specified symbolically. A typical model has the form `response ~ terms` where `response` is the (numeric) response vector and `terms` is a series of terms which specifies a linear predictor for `response`. A terms specification of the form `first + second` indicates all the terms in `first` together with all the terms in `second` with duplicates removed. A specification of the form `first:second` indicates the set of terms obtained by taking the interactions of all terms in `first` with all terms in `second`. The specification `first*second` indicates the *cross* of `first` and `second`. This is the same as `first + second + first:second`.

If the formula includes an `offset`, this is evaluated and subtracted from the response.

If `response` is a matrix a linear model is fitted separately by least-squares to each column of the matrix and the result inherits from `"mlm"` (“multivariate linear model”).

See `model.matrix` for some further details. The terms in the formula will be re-ordered so that main effects come first, followed by the interactions, all second-order, all third-order and so on; to avoid this pass a terms object as the formula (see `avov` and `demo(glm.vr)` for an example).

A formula has an implied intercept term. To remove this use either `y ~ x - 1` or `y ~ 0 + x`. See `formula` for more details of allowed formulae.

Non-`NULL` `weights` can be used to indicate that different observations have different variances (with the values in `weights` being inversely proportional to the variances); or equivalently, when the elements of `weights` are positive integers  $w_i$ , that each response  $y_i$  is the mean of  $w_i$  unit-weight observations (including the case that there are  $w_i$  observations equal to  $y_i$  and the data have been summarized). However, in the latter case, notice that within-group variation is not used. Therefore, the sigma estimate and residual degrees of freedom may be suboptimal; in the case of replication weights, even wrong. Hence, standard errors and analysis of variance tables should be treated with care.

`lm` calls the lower level functions `lm.fit`, etc, see below, for the actual numerical computations. For programming only, you may consider doing likewise.

All of `weights`, `subset` and `offset` are evaluated in the same way as variables in formula, that is first in data and then in the environment of formula.

**Value**

lm returns an object of `class` "lm" or for multivariate ('multiple') responses of class `c("mlm", "lm")`.

The functions `summary` and `anova` are used to obtain and print a summary and analysis of variance table of the results. The generic accessor functions `coefficients`, `effects`, `fitted.values` and `residuals` extract various useful features of the value returned by `lm`.

An object of class "lm" is a list containing at least the following components:

|                            |                                                                                                   |
|----------------------------|---------------------------------------------------------------------------------------------------|
| <code>coefficients</code>  | a named vector of coefficients                                                                    |
| <code>residuals</code>     | the residuals, that is response minus fitted values.                                              |
| <code>fitted.values</code> | the fitted mean values.                                                                           |
| <code>rank</code>          | the numeric rank of the fitted linear model.                                                      |
| <code>weights</code>       | (only for weighted fits) the specified weights.                                                   |
| <code>df.residual</code>   | the residual degrees of freedom.                                                                  |
| <code>call</code>          | the matched call.                                                                                 |
| <code>terms</code>         | the <code>terms</code> object used.                                                               |
| <code>contrasts</code>     | (only where relevant) the contrasts used.                                                         |
| <code>xlevels</code>       | (only where relevant) a record of the levels of the factors used in fitting.                      |
| <code>offset</code>        | the offset used (missing if none were used).                                                      |
| <code>y</code>             | if requested, the response used.                                                                  |
| <code>x</code>             | if requested, the model matrix used.                                                              |
| <code>model</code>         | if requested (the default), the model frame used.                                                 |
| <code>na.action</code>     | (where relevant) information returned by <code>model.frame</code> on the special handling of NAs. |

In addition, non-null fits will have components `assign`, `effects` and (unless not requested) `qr` relating to the linear fit, for use by extractor functions such as `summary` and `effects`.

**Using time series**

Considerable care is needed when using `lm` with time series.

Unless `na.action = NULL`, the time series attributes are stripped from the variables before the regression is done. (This is necessary as omitting NAs would invalidate the time series attributes, and if NAs are omitted in the middle of the series the result would no longer be a regular time series.)

Even if the time series attributes are retained, they are not used to line up series, so that the time shift of a lagged or differenced regressor would be ignored. It is good practice to prepare a data argument by `ts.intersect(..., dframe = TRUE)`, then apply a suitable `na.action` to that data frame and call `lm` with `na.action = NULL` so that residuals and fitted values are time series.

**Author(s)**

The design was inspired by the S function of the same name described in Chambers (1992). The implementation of model formula by Ross Ihaka was based on Wilkinson & Rogers (1973).

## Description

These are the basic computing engines called by `lm` used to fit linear models. As they work directly with numeric matrices, they may be more efficient, notably in the case of performing many similar regressions or when inference is not of interest.

`lm` calls `lm.fit()` as a helper function.

`.lm.fit()` is a thin wrapper to the "innermost" C code performing the QR decomposition without much checking and should hence be used with care. The same C code is called by `lm.fit()` and also by `glm.fit()` and `lsfit()`.

## Usage

```
lm.fit(x, y, offset = NULL, method = "qr", tol = 1e-7,
       singular.ok = TRUE, ...)
```

```
lm.wfit(x, y, w, offset = NULL, method = "qr", tol = 1e-7,
        singular.ok = TRUE, ...)
```

```
.lm.fit(x, y, tol = 1e-7)
```

## Arguments

|                          |                                                                                                                                                                                              |
|--------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>           | design matrix of dimension $n \times p$ .                                                                                                                                                    |
| <code>y</code>           | vector of observations of length $n$ , or a matrix with $n$ rows.                                                                                                                            |
| <code>w</code>           | vector of weights (length $n$ ) to be used in the fitting process for the <code>wfit</code> functions. Weighted least squares is used with weights $w$ , i.e., $\sum(w * e^2)$ is minimized. |
| <code>offset</code>      | (numeric of length $n$ ). This can be used to specify an <i>a priori</i> known component to be included in the linear predictor during fitting.                                              |
| <code>method</code>      | currently, only <code>method = "qr"</code> is supported.                                                                                                                                     |
| <code>tol</code>         | tolerance for the <code>qr</code> decomposition. Default is $1e-7$ .                                                                                                                         |
| <code>singular.ok</code> | logical. If <code>FALSE</code> , a singular model is an error.                                                                                                                               |
| <code>...</code>         | currently disregarded.                                                                                                                                                                       |

## Details

If `y` is a matrix, `offset` can be a numeric matrix of the same dimensions, in which case each column is applied to the corresponding column of `y`.

## Value

a `list` with components (for `lm.fit` and `lm.wfit`)

|                            |                                                                                                                                       |
|----------------------------|---------------------------------------------------------------------------------------------------------------------------------------|
| <code>coefficients</code>  | $p$ vector                                                                                                                            |
| <code>residuals</code>     | $n$ vector or matrix                                                                                                                  |
| <code>fitted.values</code> | $n$ vector or matrix                                                                                                                  |
| <code>effects</code>       | $n$ vector of orthogonal single-df effects. The first rank of them correspond to non-aliased coefficients, and are named accordingly. |
| <code>weights</code>       | $n$ vector — <i>only</i> for the <code>*wfit*</code> functions.                                                                       |
| <code>rank</code>          | integer, giving the rank                                                                                                              |

df.residual      degrees of freedom of residuals  
 qr                the QR decomposition, see [qr](#).

Fits without any columns or non-zero weights do not have the effects and qr components.

.lm.fit() returns a subset of the above, the qr part unwrapped, plus a logical component pivoted indicating if the underlying QR algorithm did pivot.

### Examples

```
require(utils)
set.seed(129)

n <- 7 ; p <- 2
X <- matrix(rnorm(n * p), n, p) # no intercept!
y <- rnorm(n)
w <- rnorm(n)^2

str(lmw <- lm.wfit(x = X, y = y, w = w))

str(lm. <- lm.fit (x = X, y = y))

## fits w/o intercept:
all.equal(unname(coef(lm(y ~ X-1))),
          unname(coef( lm.fit(X,y))))
all.equal(unname(coef( lm.fit(X,y))),
          coef(.lm.fit(X,y)))

if(require("microbenchmark")) {
  mb <- microbenchmark(lm(y~X-1), lm.fit(X,y), .lm.fit(X,y))
  print(mb)
  boxplot(mb, notch=TRUE)
}
```

---

lm.influence

*Regression Diagnostics*

---

### Description

This function provides the basic quantities which are used in forming a wide variety of diagnostics for checking the quality of regression fits.

### Usage

```
influence(model, ...)
## S3 method for class 'lm'
influence(model, do.coef = TRUE, ...)
## S3 method for class 'glm'
influence(model, do.coef = TRUE, ...)
```

```
lm.influence(model, do.coef = TRUE)

qr.influence(qr, res, tol = 10 * .Machine$double.eps)
```

### Arguments

|                      |                                                                                                              |
|----------------------|--------------------------------------------------------------------------------------------------------------|
| <code>model</code>   | an object as returned by <code>lm</code> or <code>glm</code> .                                               |
| <code>do.coef</code> | logical indicating if the changed coefficients (see below) are desired. These need $O(n^2p)$ computing time. |
| <code>...</code>     | further arguments passed to or from other methods.                                                           |
| <code>qr</code>      | typically the result of <code>qr()</code> , a <code>list</code> of class "qr".                               |
| <code>res</code>     | numerical vector of model residuals.                                                                         |
| <code>tol</code>     | non-negative numerical tolerance.                                                                            |

### Details

The `influence.measures()` and other functions listed in **See Also** provide a more user oriented way of computing a variety of regression diagnostics. These all build on `lm.influence`. Note that for GLMs (other than the Gaussian family with identity link) these are based on one-step approximations which may be inadequate if a case has high influence.

An attempt is made to ensure that computed hat values that are probably one are treated as one, and the corresponding rows in `sigma` and coefficients are NaN. (Dropping such a case would normally result in a variable being dropped, so it is not possible to give simple drop-one diagnostics.)

`naresid` is applied to the results and so will fill in with NAs if the fit had `na.action = na.exclude`.

`qr.influence()` is a *low level* interface to parts of `lm.influence(*, do.coef = FALSE)` provided for cases where speed is more important than user safety.

### Value

A list containing the following components of the same length or number of rows  $n$ , which is the number of non-zero weights. Cases omitted in the fit are omitted unless a `na.action` method was used (such as `na.exclude`) which restores them.

|                           |                                                                                                                                                                                                                                                        |
|---------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>hat</code>          | a vector containing the diagonal of the 'hat' matrix.                                                                                                                                                                                                  |
| <code>coefficients</code> | (unless <code>do.coef</code> is false) a matrix whose $i$ -th row contains the change in the estimated coefficients which results when the $i$ -th case is dropped from the regression. Note that aliased coefficients are not included in the matrix. |
| <code>sigma</code>        | a vector whose $i$ -th element contains the estimate of the residual standard deviation obtained when the $i$ -th case is dropped from the regression. (The approximations needed for GLMs can result in this being NaN.)                              |
| <code>wt.res</code>       | a vector of <i>weighted</i> (or for class <code>glm</code> rather <i>deviance</i> ) residuals.                                                                                                                                                         |

`qr.influence()` returns list with the two components `hat` and `sigma`, as above but without `names`.

**Note**

The coefficients returned by the R version of `lm.influence` differ from those computed by S. Rather than returning the coefficients which result from dropping each case, we return the changes in the coefficients. This is more directly useful in many diagnostic measures.

Since these need  $O(np^2)$  computing time, they can be omitted by `do.coef = FALSE`.

Note that cases with `weights == 0` are *dropped* (contrary to the situation in S).

If a model has been fitted with `na.action = na.exclude` (see [na.exclude](#)), cases excluded in the fit *are* considered here.

**Examples**

```
## Analysis of the life-cycle savings data
## given in Belsley, Kuh and Welsch.
summary(lm.SR <- lm(sr ~ pop15 + pop75 + dpi + ddpi,
                    data = LifeCycleSavings),
        correlation = TRUE)
utils::str(lmI <- lm.influence(lm.SR))

qRes <- qr(lm.SR) # == lm.SR $ qr
qrI <- qr.influence(qRes, residuals(lm.SR))
strip <- function(x) lapply(lapply(x, unname), drop)
stopifnot(identical(strip(qrI),
                     strip(lmI[c("hat", "sigma")]))))

## For more "user level" examples, use example(influence.measures)
```

**Description**

All these functions are [methods](#) for class "lm" objects.

**Usage**

```
## S3 method for class 'lm'
family(object, ...)

## S3 method for class 'lm'
formula(x, ...)

## S3 method for class 'lm'
residuals(object,
           type = c("working", "response", "deviance", "pearson",
                    "partial"),
           ...)

## S3 method for class 'lm'
labels(object, ...)
```

**Arguments**

|           |                                                                                                                         |
|-----------|-------------------------------------------------------------------------------------------------------------------------|
| object, x | an object inheriting from class <code>lm</code> , usually the result of a call to <code>lm</code> or <code>aov</code> . |
| ...       | further arguments passed to or from other methods.                                                                      |
| type      | the type of residuals which should be returned. Can be abbreviated.                                                     |

**Details**

The generic accessor functions `coef`, `effects`, `fitted` and `residuals` can be used to extract various useful features of the value returned by `lm`.

The working and response residuals are ‘observed - fitted’. The deviance and Pearson residuals are weighted residuals, scaled by the square root of the weights used in fitting. The partial residuals are a matrix with each column formed by omitting a term from the model. In all these, zero weight cases are never omitted (as opposed to the standardized `rstudent` residuals, and the `weighted.residuals`).

How residuals treats cases with missing values in the original fit is determined by the `na.action` argument of that fit. If `na.action = na.omit` omitted cases will not appear in the residuals, whereas if `na.action = na.exclude` they will appear, with residual value NA. See also `naresid`.

The “`lm`” method for generic `labels` returns the term labels for estimable terms, that is the names of the terms with an least one estimable coefficient.

`influence.measures` for deletion diagnostics, including standardized (`rstandard`) and studentized (`rstudent`) residuals.

## Examples

```
##-- Continuing the lm(.) example:
coef(lm.D90) # the bare coefficients

## The 2 basic regression diagnostic plots [plot.lm(.) is preferred]
plot(resid(lm.D90), fitted(lm.D90)) # Tukey-Anscombe's
abline(h = 0, lty = 2, col = "gray")

qqnorm(residuals(lm.D90))
```

loadings

---

*Print Factor Analysis factanal(), Notably Loadings*

---

## Description

Print factor analysis result, [factanal\(\)](#); extract or print loadings in factor analysis (or principal components analysis, PCA).

## Usage

```
loadings(x, ...)

## S3 method for class 'loadings'
print(x, digits = 3, cutoff = 0.1, sort = FALSE, ...)

## S3 method for class 'factanal'
print(x, digits = 3, ...)
```

## Arguments

|                     |                                                                                                                                                                                                                                                                                                      |
|---------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>      | an object of class " <a href="#">factanal</a> " or " <a href="#">princomp</a> " or the loadings component of such an object.                                                                                                                                                                         |
| <code>digits</code> | number of decimal places to use in printing uniquenesses and loadings.                                                                                                                                                                                                                               |
| <code>cutoff</code> | loadings smaller than this (in absolute value) are suppressed.                                                                                                                                                                                                                                       |
| <code>sort</code>   | logical. If true, the variables are sorted by their importance on each factor. Each variable with any loading larger than 0.5 (in modulus) is assigned to the factor with the largest loading, and the variables are printed in the order of the factor they are assigned to, then those unassigned. |
| <code>...</code>    | further arguments for other methods; for <a href="#">factanal</a> printing, notably passed to <code>print(&lt;loadings&gt;, ...)</code> , hence, e.g., <code>cutoff = &lt;frac&gt;</code> ; ignored for <a href="#">loadings</a> .                                                                   |

## Details

‘Loadings’ is a term from *factor analysis*, but because factor analysis and principal component analysis (PCA) are often conflated in the social science literature, it was used for PCA by SPSS and hence by [princomp](#) in S-PLUS to help SPSS users.

Small loadings are conventionally not printed (replaced by spaces), to draw the eye to the pattern of the larger loadings.

The print method for class "[factanal](#)" calls the "loadings" method to print the loadings, and so passes down arguments such as cutoff and sort.

The signs of the loadings vectors are arbitrary for both factor analysis and PCA.

### Note

There are other functions called loadings in contributed packages which are S3 or S4 generic: the ... argument is to make it easier for this one to become a default method.

|       |                                            |
|-------|--------------------------------------------|
| loess | <i>Local Polynomial Regression Fitting</i> |
|-------|--------------------------------------------|

---

### Description

Fit a locally polynomial surface determined by one or more numerical predictors, using local fitting.

### Usage

```
loess(formula, data, weights, subset, na.action, model = FALSE,
      span = 0.75, enp.target, degree = 2,
      parametric = FALSE, drop.square = FALSE, normalize = TRUE,
      family = c("gaussian", "symmetric"),
      method = c("loess", "model.frame"),
      control = loess.control(...), ...)
```

### Arguments

|            |                                                                                                                                                                                                                                                                                          |
|------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| formula    | a <a href="#">formula</a> specifying the numeric response and one to four numeric predictors (best specified via an interaction, but can also be specified additively). Will be coerced to a formula if necessary.                                                                       |
| data       | an optional data frame, list or environment (or object coercible by <a href="#">as.data.frame</a> to a data frame) containing the variables in the model. If not found in data, the variables are taken from environment(formula), typically the environment from which loess is called. |
| weights    | optional weights for each case.                                                                                                                                                                                                                                                          |
| subset     | an optional specification of a subset of the data to be used.                                                                                                                                                                                                                            |
| na.action  | the action to be taken with missing values in the response or predictors. The default is given by <code>getOption("na.action")</code> .                                                                                                                                                  |
| model      | should the model frame be returned?                                                                                                                                                                                                                                                      |
| span       | the parameter $\alpha$ which controls the degree of smoothing.                                                                                                                                                                                                                           |
| enp.target | an alternative way to specify span, as the approximate equivalent number of parameters to be used.                                                                                                                                                                                       |
| degree     | the degree of the polynomials to be used, normally 1 or 2. (Degree 0 is also allowed, but see the 'Note'.)                                                                                                                                                                               |

|                          |                                                                                                                                                                                                                                                       |
|--------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>parametric</code>  | should any terms be fitted globally rather than locally? Terms can be specified by name, number or as a logical vector of the same length as the number of predictors.                                                                                |
| <code>drop.square</code> | for fits with more than one predictor and <code>degree = 2</code> , should the quadratic term be dropped for particular predictors? Terms are specified in the same way as for <code>parametric</code> .                                              |
| <code>normalize</code>   | should the predictors be normalized to a common scale if there is more than one? The normalization used is to set the 10% trimmed standard deviation to one. Set to false for spatial coordinate predictors and others known to be on a common scale. |
| <code>family</code>      | if "gaussian" fitting is by least-squares, and if "symmetric" a re-descending M estimator is used with Tukey's biweight function. Can be abbreviated.                                                                                                 |
| <code>method</code>      | fit the model or just extract the model frame. Can be abbreviated.                                                                                                                                                                                    |
| <code>control</code>     | control parameters: see <a href="#">loess.control</a> .                                                                                                                                                                                               |
| <code>...</code>         | control parameters can also be supplied directly (if <code>control</code> is not specified).                                                                                                                                                          |

### Details

Fitting is done locally. That is, for the fit at point  $x$ , the fit is made using points in a neighbourhood of  $x$ , weighted by their distance from  $x$  (with differences in 'parametric' variables being ignored when computing the distance). The size of the neighbourhood is controlled by  $\alpha$  (set by `span` or `enp.target`). For  $\alpha < 1$ , the neighbourhood includes proportion  $\alpha$  of the points, and these have tricubic weighting (proportional to  $(1 - (\text{dist}/\text{maxdist})^3)^3$ ). For  $\alpha > 1$ , all points are used, with the 'maximum distance' assumed to be  $\alpha^{1/p}$  times the actual maximum distance for  $p$  explanatory variables.

For the default family, fitting is by (weighted) least squares. For `family="symmetric"` a few iterations of an M-estimation procedure with Tukey's biweight are used. Be aware that as the initial value is the least-squares fit, this need not be a very resistant fit.

It can be important to tune the control list to achieve acceptable speed. See [loess.control](#) for details.

### Value

An object of class "loess", with `print()`, `summary()`, `predict` and `anova` methods.

### Note

As this is based on `cloess`, it is similar to but not identical to the `loess` function of S. In particular, conditioning is not implemented.

The memory usage of this implementation of `loess` is roughly quadratic in the number of points, with 1000 points taking about 10Mb.

`degree = 0`, local constant fitting, is allowed in this implementation but not documented in the reference. It seems very little tested, so use with caution.

### Author(s)

B. D. Ripley, based on the `cloess` package of Cleveland, Grosse and Shyu.

### Source

The 1998 version of `cloess` package of Cleveland, Grosse and Shyu. A later version is available as `dloess` at <https://netlib.org/a/>.

|---------------|---------------------------------|
| loess.control | <i>Set Parameters for loess</i> |
|---------------|---------------------------------|

---

Description

Set control parameters for loess fits.

Usage

```
loess.control(surface = c("interpolate", "direct"),
              statistics = c("approximate", "exact", "none"),
              trace.hat = c("exact", "approximate"),
              cell = 0.2, iterations = 4, iterTrace = FALSE, ...)
```

Arguments

|            |                                                                                                                                                                                                                                                                       |
|------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| surface    | should the fitted surface be computed exactly ("direct") or via interpolation from a k-d tree? Can be abbreviated.                                                                                                                                                    |
| statistics | should the statistics be computed exactly, approximately or not at all? Exact computation can be very slow. Can be abbreviated.                                                                                                                                       |
| trace.hat  | Only for the (default) case (surface = "interpolate", statistics = "approximate"): should the trace of the smoother matrix be computed exactly or approximately? It is recommended to use the approximation for more than about 1000 data points. Can be abbreviated. |
| cell       | if interpolation is used this controls the accuracy of the approximation via the maximum number of points in a cell in the k-d tree. Cells with more than floor(n*span*cell) points are subdivided.                                                                   |
| iterations | the number of iterations used in robust fitting, i.e. only if family is "symmetric".                                                                                                                                                                                  |
| iterTrace  | logical (or integer) determining if tracing information during the robust iterations (iterations ≥ 2) is produced.                                                                                                                                                    |
| ...        | further arguments which are ignored.                                                                                                                                                                                                                                  |

**Value**

Logistic

*The Logistic Distribution*

---

**Description**

Density, distribution function, quantile function and random generation for the logistic distribution with parameters location and scale.

**Usage**

```
dlogis(x, location = 0, scale = 1, log = FALSE)
plogis(q, location = 0, scale = 1, lower.tail = TRUE, log.p = FALSE)
qlogis(p, location = 0, scale = 1, lower.tail = TRUE, log.p = FALSE)
rlogis(n, location = 0, scale = 1)
```

**Arguments**

|                 |                                                                                                           |
|-----------------|-----------------------------------------------------------------------------------------------------------|
| x, q            | vector of quantiles.                                                                                      |
| p               | vector of probabilities.                                                                                  |
| n               | number of observations. If <code>length(n) &gt; 1</code> , the length is taken to be the number required. |
| location, scale | location and scale parameters.                                                                            |
| log, log.p      | logical; if TRUE, probabilities p are given as $\log(p)$ .                                                |
| lower.tail      | logical; if TRUE (default), probabilities are $P[X \leq x]$ , otherwise, $P[X > x]$ .                     |

**Details**

If location or scale are omitted, they assume the default values of 0 and 1 respectively.

The Logistic distribution with location =  $\mu$  and scale =  $\sigma$  has distribution function

$$F(x) = \frac{1}{1 + e^{-(x-\mu)/\sigma}}$$

and density

$$f(x) = \frac{1}{\sigma} \frac{e^{(x-\mu)/\sigma}}{(1 + e^{(x-\mu)/\sigma})^2}$$

It is a long-tailed distribution with mean  $\mu$  and variance  $\pi^2/3\sigma^2$ .

**Value**

dlogis gives the density, plogis gives the distribution function, qlogis gives the quantile function, and rlogis generates random deviates.

The length of the result is determined by n for rlogis, and is the maximum of the lengths of the numerical arguments for the other functions.

The numerical arguments other than n are recycled to the length of the result. Only the first elements of the logical arguments are used.

**Note**

qlogis(p) is the same as the well known ‘logit’ function,  $\text{logit}(p) = \log p/(1-p)$ , and plogis(x) has consequently been called the ‘inverse logit’.

The distribution function is a rescaled hyperbolic tangent,  $\text{plogis}(x) == (1 + \tanh(x/2))/2$ , and it is called a *sigmoid function* in contexts such as neural networks.

**Source**

[dpq]logis are calculated directly from the definitions.

rlogis uses inversion.

pi^2/3 * 5^2
```

logLik

*Extract Log-Likelihood***Description**

This function is generic; method functions can be written to handle specific classes of objects. Classes which have methods for this function include: "glm", "lm", "nls" and "Arima". Packages contain methods for other classes, such as "fitdistr", "negbin" and "polr" in package **MASS**, "multinom" in package **nnet** and "gls", "gnls" "lme" and others in package **nlme**.

**Usage**

```
logLik(object, ...)

## S3 method for class 'lm'
logLik(object, REML = FALSE, ...)
```

**Arguments**

|        |                                                                                                                                                  |
|--------|--------------------------------------------------------------------------------------------------------------------------------------------------|
| object | any object from which a log-likelihood value, or a contribution to a log-likelihood value, can be extracted.                                     |
| ...    | some methods for this generic function require additional arguments.                                                                             |
| REML   | an optional logical value. If TRUE the restricted log-likelihood is returned, else, if FALSE, the log-likelihood is returned. Defaults to FALSE. |

**Details**

logLik is most commonly used for a model fitted by maximum likelihood, and some uses, e.g. by [AIC](#), assume this. So care is needed where other fit criteria have been used, for example REML (the default for "lme").

For a "glm" fit the [family](#) does not have to specify how to calculate the log-likelihood, so this is based on using the family's `aic()` function to compute the AIC. For the [gaussian](#), [Gamma](#) and [inverse.gaussian](#) families it is assumed that the dispersion of the GLM is estimated and has been counted as a parameter in the AIC value, and for all other families it is assumed that the dispersion is known. Note that this procedure does not give the maximized likelihood for "glm" fits from the Gamma and inverse gaussian families, as the estimate of dispersion used is not the MLE.

For "lm" fits it is assumed that the scale has been estimated (by maximum likelihood or REML), and all the constants in the log-likelihood are included. That method is only applicable to single-response fits.

**Value**

Returns an object of class logLik. This is a number with at least one attribute, "df" (**d**egrees of **f**reedom), giving the number of (estimated) parameters in the model.

There is a simple print method for "logLik" objects.

There may be other attributes depending on the method used: see the appropriate documentation. One that is used by several methods is "nobs", the number of observations used in estimation (after the restrictions if REML = TRUE).

|--------|----------------------------------|
| loglin | <i>Fitting Log-Linear Models</i> |
|--------|----------------------------------|

---

Description

loglin is used to fit log-linear models to multidimensional contingency tables by Iterative Proportional Fitting.

Usage

```
loglin(table, margin, start = rep(1, length(table)), fit = FALSE,
       eps = 0.1, iter = 20, param = FALSE, print = TRUE)
```

Arguments

- table            a contingency table to be fit, typically the output from table.
- margin          a list of vectors with the marginal totals to be fit.  
(Hierarchical) log-linear models can be specified in terms of these marginal totals which give the ‘maximal’ factor subsets contained in the model. For example, in a three-factor model, list(c(1, 2), c(1, 3)) specifies a model which

contains parameters for the grand mean, each factor, and the 1-2 and 1-3 interactions, respectively (but no 2-3 or 1-2-3 interaction), i.e., a model where factors 2 and 3 are independent conditional on factor 1 (sometimes represented as '[12][13]').

The names of factors (i.e., `names(dimnames(table))`) may be used rather than numeric indices. Or `NULL` or `list()` to specify fitting no margins.

|                    |                                                                                                                                                                                                                                                                                                        |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>start</code> | a starting estimate for the fitted table. This optional argument is important for incomplete tables with structural zeros in <code>table</code> which should be preserved in the fit. In this case, the corresponding entries in <code>start</code> should be zero and the others can be taken as one. |
| <code>fit</code>   | a logical indicating whether the fitted values should be returned.                                                                                                                                                                                                                                     |
| <code>eps</code>   | bound for allowed deviation (largest absolute value of the difference) between observed and fitted margins.                                                                                                                                                                                            |
| <code>iter</code>  | maximum number of iterations.                                                                                                                                                                                                                                                                          |
| <code>param</code> | a logical indicating whether the parameter values should be returned.                                                                                                                                                                                                                                  |
| <code>print</code> | a logical. If <code>TRUE</code> , the number of iterations and the final deviation (if there were any iterations) are printed.                                                                                                                                                                         |

## Details

The Iterative Proportional Fitting algorithm as presented in Haberman (1972) is used for fitting the model. At most `iter` iterations are performed, convergence is taken to occur when the maximum deviation between observed and fitted margins is less than `eps`. All internal computations are done in double precision; there is no limit on the number of factors (the dimension of the table) in the model.

Assuming that there are no structural zeros, both the Likelihood Ratio Test and Pearson test statistics have an asymptotic chi-squared distribution with `df` degrees of freedom.

Note that the IPF steps are applied to the factors in the order given in `margin`. Hence if the model is decomposable and the order given in `margin` is a running intersection property ordering then IPF will converge in one iteration.

Package **MASS** contains `loglm`, a front-end to `loglin` which allows the log-linear model to be specified and fitted in a formula-based manner similar to that of other fitting functions such as `lm` or `glm`.

## Value

A list with the following components.

|                      |                                                                                                                                                                                                                                                |
|----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>lrt</code>     | the Likelihood Ratio Test statistic.                                                                                                                                                                                                           |
| <code>pearson</code> | the Pearson test statistic (X-squared).                                                                                                                                                                                                        |
| <code>df</code>      | the degrees of freedom for the fitted model. There is no adjustment for structural zeros.                                                                                                                                                      |
| <code>margin</code>  | list of the margins that were fit. Basically the same as the input <code>margin</code> , but with numbers replaced by names where possible. Will be <code>NULL</code> if the input is.                                                         |
| <code>fit</code>     | An array like <code>table</code> containing the fitted values. Only returned if <code>fit</code> is <code>TRUE</code> .                                                                                                                        |
| <code>param</code>   | A list containing the estimated parameters of the model. The 'standard' constraints of zero marginal sums (e.g., zero row and column sums for a two factor parameter) are employed. Only returned if <code>param</code> is <code>TRUE</code> . |

|-----------|------------------------------------|
| Lognormal | <i>The Log Normal Distribution</i> |
|-----------|------------------------------------|

---

Description

Density, distribution function, quantile function and random generation for the log normal distribution whose logarithm has mean equal to meanlog and standard deviation equal to sdlog.

Usage

```
dlnorm(x, meanlog = 0, sdlog = 1, log = FALSE)
plnorm(q, meanlog = 0, sdlog = 1, lower.tail = TRUE, log.p = FALSE)
qlnorm(p, meanlog = 0, sdlog = 1, lower.tail = TRUE, log.p = FALSE)
rlnorm(n, meanlog = 0, sdlog = 1)
```

Arguments

|                |                                                                                                               |
|----------------|---------------------------------------------------------------------------------------------------------------|
| x, q           | vector of quantiles.                                                                                          |
| p              | vector of probabilities.                                                                                      |
| n              | number of observations. If length(n) > 1, the length is taken to be the number required.                      |
| meanlog, sdlog | mean and standard deviation of the distribution on the log scale with default values of 0 and 1 respectively. |
| log, log.p     | logical; if TRUE, probabilities p are given as log(p).                                                        |
| lower.tail     | logical; if TRUE (default), probabilities are $P[X \leq x]$ , otherwise, $P[X > x]$ .                         |

## Details

The log normal distribution has density

$$f(x) = \frac{1}{\sqrt{2\pi}\sigma x} e^{-(\log(x)-\mu)^2/2\sigma^2}$$

where  $\mu$  and  $\sigma$  are the mean and standard deviation of the logarithm. The mean is  $E(X) = \exp(\mu + 1/2\sigma^2)$ , the median is  $\text{med}(X) = \exp(\mu)$ , and the variance  $\text{Var}(X) = \exp(2\mu + \sigma^2)(\exp(\sigma^2) - 1)$  and hence the coefficient of variation is  $\sqrt{\exp(\sigma^2) - 1}$  which is approximately  $\sigma$  when that is small (e.g.,  $\sigma < 1/2$ ).

## Value

`dlnorm` gives the density, `plnorm` gives the distribution function, `qlnorm` gives the quantile function, and `rlnorm` generates random deviates.

The length of the result is determined by `n` for `rlnorm`, and is the maximum of the lengths of the numerical arguments for the other functions.

The numerical arguments other than `n` are recycled to the length of the result. Only the first elements of the logical arguments are used.

## Note

The cumulative hazard  $H(t) = -\log(1 - F(t))$  is `-plnorm(t, r, lower = FALSE, log = TRUE)`.

## Source

`dlnorm` is calculated from the definition (in ‘Details’). `[pqr]lnorm` are based on the relationship to the normal.

Consequently, they model a single point mass at  $\exp(\text{meanlog})$  for the boundary case  $\text{sdlog} = 0$ .

## Examples

```
dlnorm(1) == dnorm(0)
```

lowess

Scatter Plot Smoothing

**Description**

This function performs the computations for the *LOWESS* smoother which uses locally-weighted polynomial regression (see the references).

**Usage**

```
lowess(x, y = NULL, f = 2/3, iter = 3, delta = 0.01 * diff(range(x)))
```

**Arguments**

|                    |                                                                                                                                                                |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x, y</code>  | vectors giving the coordinates of the points in the scatter plot. Alternatively a single plotting structure can be specified – see <a href="#">xy.coords</a> . |
| <code>f</code>     | the smoother span. This gives the proportion of points in the plot which influence the smooth at each value. Larger values give more smoothness.               |
| <code>iter</code>  | the number of ‘robustifying’ iterations which should be performed. Using smaller values of <code>iter</code> will make <code>lowess</code> run faster.         |
| <code>delta</code> | See ‘Details’. Defaults to 1/100th of the range of <code>x</code> .                                                                                            |

**Details**

`lowess` is defined by a complex algorithm, the Ratfor original of which (by W. S. Cleveland) can be found in the R sources as file ‘src/library/stats/src/lowess.doc’. Normally a local linear polynomial fit is used, but under some circumstances (see the file) a local constant fit can be used. ‘Local’ is defined by the distance to the  $\text{floor}(f \cdot n)$ -th nearest neighbour, and tricubic weighting is used for `x` which fall within the neighbourhood.

The initial fit is done using weighted least squares. If `iter > 0`, further weighted fits are done using the product of the weights from the proximity of the `x` values and case weights derived from the residuals at the previous iteration. Specifically, the case weight is Tukey’s biweight, with cutoff 6 times the MAD of the residuals. (The current R implementation differs from the original in stopping iteration if the MAD is effectively zero since the algorithm is highly unstable in that case.)

`delta` is used to speed up computation: instead of computing the local polynomial fit at each data point it is not computed for points within `delta` of the last computed point, and linear interpolation is used to fill in the fitted values for the skipped points.

**Value**

`lowess` returns a list containing components `x` and `y` which give the coordinates of the smooth. The smooth can be added to a plot of the original points with the function `lines`: see the examples.

require(graphics)

plot(cars, main = "lowess(cars)")
lines(lowess(cars), col = 2)
lines(lowess(cars, f = .2), col = 3)
legend(5, 120, c(paste("f = ", c("2/3", ".2"))), lty = 1, col = 2:3)
```

ls.diag

*Compute Diagnostics for lsfit Regression Results***Description**

Computes basic statistics, including standard errors, t- and p-values for the regression coefficients.

**Usage**

```
ls.diag(ls.out)
```

**Arguments**

ls.out            Typically the result of [lsfit\(\)](#)

**Value**

A list with the following numeric components.

|              |                                                                 |
|--------------|-----------------------------------------------------------------|
| std.dev      | The standard deviation of the errors, an estimate of $\sigma$ . |
| hat          | diagonal entries $h_{ii}$ of the hat matrix $H$                 |
| std.res      | standardized residuals                                          |
| stud.res     | studentized residuals                                           |
| cooks        | Cook's distances                                                |
| dfits        | DFITS statistics                                                |
| correlation  | correlation matrix                                              |
| std.err      | standard errors of the regression coefficients                  |
| cov.scaled   | Scaled covariance matrix of the coefficients                    |
| cov.unscaled | Unscaled covariance matrix of the coefficients                  |

Examples

```
##-- Using the same data as the lm(.) example:
lsD9 <- lsfit(x = as.numeric(gl(2, 10, 20)), y = weight)
dlsD9 <- ls.diag(lsD9)
utils::str(dlsD9, give.attr = FALSE)
abs(1 - sum(dlsD9$hat) / 2) < 10*.Machine$double.eps # sum(h.ii) = p
plot(dlsD9$hat, dlsD9$stud.res, xlim = c(0, 0.11))
abline(h = 0, lty = 2, col = "lightgray")
```

---

|          |                                       |
|----------|---------------------------------------|
| ls.print | <i>Print lsfit Regression Results</i> |
|----------|---------------------------------------|

---

Description

Computes basic statistics, including standard errors, t- and p-values for the regression coefficients and prints them if `print.it` is TRUE.

Usage

```
ls.print(ls.out, digits = 4, print.it = TRUE)
```

Arguments

|          |                                                                |
|----------|----------------------------------------------------------------|
| ls.out   | Typically the result of <code>lsfit()</code>                   |
| digits   | The number of significant digits used for printing             |
| print.it | a logical indicating whether the result should also be printed |

Value

|                            |                                                                       |
|----------------------------|-----------------------------------------------------------------------|
| A list with the components |                                                                       |
| summary                    | The ANOVA table of the regression                                     |
| coef.table                 | matrix with regression coefficients, standard errors, t- and p-values |

Note

Usually you would use `summary(lm(...))` and `anova(lm(...))` to obtain similar output.

See Also

`ls.diag`, `lsfit`, also for examples; `lm`, `lm.influence` which usually are preferable.

lsfit

*Find the Least Squares Fit***Description**

The least squares estimate of  $\beta$  in the model

$$Y = X\beta + \epsilon$$

is found.

**Usage**

```
lsfit(x, y, wt = NULL, intercept = TRUE, tolerance = 1e-07,
      yname = NULL)
```

**Arguments**

|           |                                                                                    |
|-----------|------------------------------------------------------------------------------------|
| x         | a matrix whose rows correspond to cases and whose columns correspond to variables. |
| y         | the responses, possibly a matrix if you want to fit multiple left hand sides.      |
| wt        | an optional vector of weights for performing weighted least squares.               |
| intercept | whether or not an intercept term should be used.                                   |
| tolerance | the tolerance to be used in the matrix decomposition.                              |
| yname     | names to be used for the response variables.                                       |

**Details**

If weights are specified then a weighted least squares is performed with the weight given to the  $j$ -th case specified by the  $j$ -th entry in wt.

If any observation has a missing value in any field, that observation is removed before the analysis is carried out. This can be quite inefficient if there is a lot of missing data.

The implementation is via a modification of the LINPACK subroutines which allow for multiple left-hand sides.

**Value**

A list with the following named components:

|           |                                                                                          |
|-----------|------------------------------------------------------------------------------------------|
| coef      | the least squares estimates of the coefficients in the model ( $\beta$ as stated above). |
| residuals | residuals from the fit.                                                                  |
| intercept | indicates whether an intercept was fitted.                                               |
| qr        | the QR decomposition of the design matrix.                                               |

**References**

Becker, R. A., Chambers, J. M. and Wilks, A. R. (1988) *The New S Language*. Wadsworth & Brooks/Cole.

|     |                                  |
|-----|----------------------------------|
| mad | <i>Median Absolute Deviation</i> |
|-----|----------------------------------|

---

**Description**

Compute the median absolute deviation, i.e., the (lo-/hi-) median of the absolute deviations from the median (or another center), and (by default) adjust by a factor for asymptotically normal consistency.

**Usage**

```
mad(x, center = median(x), constant = 1.4826, na.rm = FALSE,
    low = FALSE, high = FALSE)
```

**Arguments**

|                       |                                                                                                                                                          |
|-----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>        | a numeric vector.                                                                                                                                        |
| <code>center</code>   | optionally, a number, the centre: defaults to the median.                                                                                                |
| <code>constant</code> | scale factor.                                                                                                                                            |
| <code>na.rm</code>    | if TRUE then NA values are stripped from <code>x</code> before computation takes place.                                                                  |
| <code>low</code>      | if TRUE, compute the ‘lo-median’ of the absolute deviations, i.e., for even sample size, do not average the two middle values, but take the smaller one. |
| <code>high</code>     | if TRUE, compute the ‘hi-median’ of $ x - \text{center} $ , i.e., take the larger of the two middle values for even sample size.                         |

**Details**

The actual value calculated is `constant * cMedian(abs(x - center))` with the default value of `center` being `median(x)`, and `cMedian` being the usual, the ‘low’ or ‘high’ median, see the arguments description for `low` and `high` above.

In the case of  $n = 1$  non-missing values and default `center`, the result is 0, consistent with “no deviation from the center”.

The default `constant = 1.4826` (approximately  $1/\Phi^{-1}(\frac{3}{4}) = 1/\text{qnorm}(3/4)$ ) ensures consistency, i.e.,

$$E[\text{mad}(X_1, \dots, X_n)] = \sigma$$

for  $X_i$  distributed as  $N(\mu, \sigma^2)$  and large  $n$ .

If `na.rm` is TRUE then NA values are stripped from `x` before computation takes place. If this is not done then an NA value in `x` will cause `mad` to return NA.

**See Also**

[IQR](#) which is simpler but less robust, [median](#), [var](#).

**Examples**

```
mad(c(1:9))
print(mad(c(1:9), constant = 1)) ==
      mad(c(1:8, 100), constant = 1)      # = 2 ; TRUE
x <- c(1,2,3,5,7,8)
sort(abs(x - median(x)))
c(mad(x, constant = 1),
  mad(x, constant = 1, low = TRUE),
  mad(x, constant = 1, high = TRUE))
```

mahalanobis

*Mahalanobis Distance***Description**

Returns the squared Mahalanobis distance of all rows in `x` and the vector  $\mu$  = center with respect to  $\Sigma$  = cov. This is (for vector `x`) defined as

$$D^2 = (x - \mu)' \Sigma^{-1} (x - \mu)$$

**Usage**

```
mahalanobis(x, center, cov, inverted = FALSE, ...)
```

**Arguments**

|                       |                                                                                                                                                                    |
|-----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>        | vector or matrix of data with, say, $p$ columns.                                                                                                                   |
| <code>center</code>   | mean vector of the distribution or second data vector of length $p$ or recyclable to that length. If set to <a href="#">FALSE</a> , the centering step is skipped. |
| <code>cov</code>      | covariance matrix ( $p \times p$ ) of the distribution.                                                                                                            |
| <code>inverted</code> | logical. If TRUE, cov is supposed to contain the <i>inverse</i> of the covariance matrix.                                                                          |
| <code>...</code>      | passed to <a href="#">solve</a> for computing the inverse of the covariance matrix (if <code>inverted</code> is false).                                            |

**Examples**

```
require(graphics)

ma <- cbind(1:6, 1:3)
(S <- var(ma))
mahalanobis(c(0, 0), 1:2, S)

x <- matrix(rnorm(100*3), ncol = 3)
stopifnot(mahalanobis(x, 0, diag(ncol(x))) == rowSums(x*x))
```

```

##- Here, D^2 = usual squared Euclidean distances

Sx <- cov(x)
D2 <- mahalanobis(x, colMeans(x), Sx)
plot(density(D2, bw = 0.5),
     main="Squared Mahalanobis distances, n=100, p=3") ; rug(D2)
qqplot(qchisq(ppoints(100), df = 3), D2,
       main = expression("Q-Q plot of Mahalanobis" * ~D^2 *
                          " vs. quantiles of" * ~chi[3]^2))
abline(0, 1, col = 'gray')

```

make.link

*Create a Link for GLM Families*

## Description

This function is used with the [family](#) functions in [glm\(\)](#). Given the name of a link, it returns a link function, an inverse link function, the derivative  $d\mu/d\eta$  and a function for domain checking.

## Usage

```
make.link(link)
```

## Arguments

|      |                                                                                                            |
|------|------------------------------------------------------------------------------------------------------------|
| link | character; one of "logit", "probit", "cauchit", "cloglog", "identity", "log", "sqrt", "1/mu^2", "inverse". |
|------|------------------------------------------------------------------------------------------------------------|

## Value

A object of class "link-glm", a list with components

|          |                                                           |
|----------|-----------------------------------------------------------|
| linkfun  | Link function function(mu)                                |
| linkinv  | Inverse link function function(eta)                       |
| mu.eta   | Derivative function(eta) $d\mu/d\eta$                     |
| valideta | function(eta){ TRUE if eta is in the domain of linkinv }. |
| name     | a name to be used for the link                            |

.

## See Also

```

makepredictcall

*Utility Function for Safe Prediction***Description**

A utility to help `model.frame.default` create the right matrices when predicting from models with terms like (univariate) `poly` or `ns`.

**Usage**

```
makepredictcall(var, call)
```

**Arguments**

`var`                    A variable.  
`call`                    The term in the formula, as a call.

**Details**

This is a generic function with methods for `poly`, `bs` and `ns`: the default method handles `scale`. If `model.frame.default` encounters such a term when creating a model frame, it modifies the `predvars` attribute of the terms supplied by replacing the term with one which will work for predicting new data. For example `makepredictcall.ns` adds arguments for the knots and intercept.

To make use of this, have your model-fitting function return the `terms` attribute of the model frame, or copy the `predvars` attribute of the `terms` attribute of the model frame to your `terms` object.

To extend this, make sure the term creates variables with a class, and write a suitable method for that class.

**Value**

A replacement for `call` for the `predvars` attribute of the terms.

**See Also**

`model.frame`, `poly`, `scale`; `bs` and `ns` in package **splines**.

`cars` for an example of prediction from a polynomial fit.

**Examples**

```
require(graphics)

## using poly: this did not work in R < 1.5.0
fm <- lm(weight ~ poly(height, 2), data = women)
plot(women, xlab = "Height (in)", ylab = "Weight (lb)")
ht <- seq(57, 73, length.out = 200)
nD <- data.frame(height = ht)
pfm <- predict(fm, nD)
lines(ht, pfm)
pf2 <- predict(update(fm, ~ stats::poly(height, 2)), nD)
stopifnot(all.equal(pfm, pf2)) ## was off (rel.diff. 0.0766) in R <= 3.5.0

## see also example(cars)
```

```
## see bs and ns for spline examples.
```

---

manova

---

*Multivariate Analysis of Variance*

---

## Description

A class for the multivariate analysis of variance.

## Usage

```
manova(...)
```

## Arguments

... Arguments to be passed to [aov](#).

## Details

Class "manova" differs from class "aov" in selecting a different summary method. Function `manova` calls [aov](#) and then add class "manova" to the result object for each stratum.

## Value

See [aov](#) and the comments in 'Details' here.

## References

Krzanowski, W. J. (1988) *Principles of Multivariate Analysis. A User's Perspective*. Oxford.

Hand, D. J. and Taylor, C. C. (1987) *Multivariate Analysis of Variance and Repeated Measures*. Chapman and Hall.

## See Also

[aov](#), [summary.manova](#), the latter containing more examples.

## Examples

```
## Set orthogonal contrasts.
op <- options(contrasts = c("contr.helmert", "contr.poly"))

## Fake a 2nd response variable
npk2 <- within(npk, foo <- rnorm(24))
( npk2.aov <- manova(cbind(yield, foo) ~ block + N*P*K, npk2) )
summary(npk2.aov)

( npk2.aovE <- manova(cbind(yield, foo) ~ N*P*K + Error(block), npk2) )
summary(npk2.aovE)
```

mantelhaen.test

*Cochran-Mantel-Haenszel Chi-Squared Test for Count Data***Description**

Performs a Cochran-Mantel-Haenszel chi-squared test of the null that two nominal variables are conditionally independent in each stratum, assuming that there is no three-way interaction.

**Usage**

```
mantelhaen.test(x, y = NULL, z = NULL,
                 alternative = c("two.sided", "less", "greater"),
                 correct = TRUE, exact = FALSE, conf.level = 0.95)
```

**Arguments**

|                          |                                                                                                                                                                                        |
|--------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>           | either a 3-dimensional contingency table in array form where each dimension is at least 2 and the last dimension corresponds to the strata, or a factor object with at least 2 levels. |
| <code>y</code>           | a factor object with at least 2 levels; ignored if <code>x</code> is an array.                                                                                                         |
| <code>z</code>           | a factor object with at least 2 levels identifying to which stratum the corresponding elements in <code>x</code> and <code>y</code> belong; ignored if <code>x</code> is an array.     |
| <code>alternative</code> | indicates the alternative hypothesis and must be one of "two.sided", "greater" or "less". You can specify just the initial letter. Only used in the 2 by 2 by $K$ case.                |
| <code>correct</code>     | a logical indicating whether to apply continuity correction when computing the test statistic. Only used in the 2 by 2 by $K$ case.                                                    |
| <code>exact</code>       | a logical indicating whether the Mantel-Haenszel test or the exact conditional test (given the strata margins) should be computed. Only used in the 2 by 2 by $K$ case.                |
| <code>conf.level</code>  | confidence level for the returned confidence interval. Only used in the 2 by 2 by $K$ case.                                                                                            |

**Details**

If `x` is an array, each dimension must be at least 2, and the entries should be nonnegative integers. NA's are not allowed. Otherwise, `x`, `y` and `z` must have the same length. Triples containing NA's are removed. All variables must take at least two different values.

**Value**

A list with class "htest" containing the following components:

|                        |                                                                                                                                                                                                                                                  |
|------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>statistic</code> | Only present if no exact test is performed. In the classical case of a 2 by 2 by $K$ table (i.e., of dichotomous underlying variables), the Mantel-Haenszel chi-squared statistic; otherwise, the generalized Cochran-Mantel-Haenszel statistic. |
| <code>parameter</code> | the degrees of freedom of the approximate chi-squared distribution of the test statistic (1 in the classical case). Only present if no exact test is performed.                                                                                  |
| <code>p.value</code>   | the p-value of the test.                                                                                                                                                                                                                         |

|             |                                                                                                                                                                                                             |
|-------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| conf.int    | a confidence interval for the common odds ratio. Only present in the 2 by 2 by $K$ case.                                                                                                                    |
| estimate    | an estimate of the common odds ratio. If an exact test is performed, the conditional Maximum Likelihood Estimate is given; otherwise, the Mantel-Haenszel estimate. Only present in the 2 by 2 by $K$ case. |
| null.value  | the common odds ratio under the null of independence, 1. Only present in the 2 by 2 by $K$ case.                                                                                                            |
| alternative | a character string describing the alternative hypothesis. Only present in the 2 by 2 by $K$ case.                                                                                                           |
| method      | a character string indicating the method employed, and whether or not continuity correction was used.                                                                                                       |
| data.name   | a character string giving the names of the data.                                                                                                                                                            |

### Note

The asymptotic distribution is only valid if there is no three-way interaction. In the classical 2 by 2 by  $K$  case, this is equivalent to the conditional odds ratios in each stratum being identical. Currently, no inference on homogeneity of the odds ratios is performed.

See also the example below.

---

mauchly.test

*Mauchly's Test of Sphericity*

---

## Description

Tests whether a Wishart-distributed covariance matrix (or transformation thereof) is proportional to a given matrix.

## Usage

```
mauchly.test(object, ...)
## S3 method for class 'mlm'
```

```

mauchly.test(object, ...)
## S3 method for class 'SSD'
mauchly.test(object, Sigma = diag(nrow = p),
              T = Thin.row(Proj(M) - Proj(X)), M = diag(nrow = p), X = ~0,
              idata = data.frame(index = seq_len(p)), ...)

```

### Arguments

|        |                                                                |
|--------|----------------------------------------------------------------|
| object | object of class SSD or <code>mlm</code> .                      |
| Sigma  | matrix to be proportional to.                                  |
| T      | transformation matrix. By default computed from M and X.       |
| M      | formula or matrix describing the outer projection (see below). |
| X      | formula or matrix describing the inner projection (see below). |
| idata  | data frame describing intra-block design.                      |
| ...    | arguments to be passed to or from other methods.               |

### Details

This is a generic function with methods for classes "`mlm`" and "`SSD`".

The basic method is for objects of class `SSD` the method for `mlm` objects just extracts the SSD matrix and invokes the corresponding method with the same options and arguments.

The `T` argument is used to transform the observations prior to testing. This typically involves transformation to intra-block differences, but more complicated within-block designs can be encountered, making more elaborate transformations necessary. A matrix `T` can be given directly or specified as the difference between two projections onto the spaces spanned by `M` and `X`, which in turn can be given as matrices or as model formulas with respect to `idata` (the tests will be invariant to parametrization of the quotient space  $M/X$ ).

The common use of this test is in repeated measurements designs, with  $X = \sim 1$ . This is almost, but not quite the same as testing for compound symmetry in the untransformed covariance matrix.

Notice that the defaults involve `p`, which is calculated internally as the dimension of the SSD matrix, and a couple of hidden functions in the **stats** namespace, namely `proj` which calculates projection matrices from design matrices or model formulas and `Thin.row` which removes linearly dependent rows from a matrix until it has full row rank.

### Value

An object of class "`htest`"

### Note

The p-value differs slightly from that of SAS because a second order term is included in the asymptotic approximation in R.

mcnemar.test

*McNemar's Chi-squared Test for Count Data*

---

## Description

Performs McNemar's chi-squared test for symmetry of rows and columns in a two-dimensional contingency table.

## Usage

```
mcnemar.test(x, y = NULL, correct = TRUE)
```

## Arguments

|         |                                                                                                |
|---------|------------------------------------------------------------------------------------------------|
| x       | either a two-dimensional contingency table in matrix form, or a factor object.                 |
| y       | a factor object; ignored if x is a matrix.                                                     |
| correct | a logical indicating whether to apply continuity correction when computing the test statistic. |

## Details

The null is that the probabilities of being classified into cells  $[i, j]$  and  $[j, i]$  are the same.

If x is a matrix, it is taken as a two-dimensional contingency table, and hence its entries should be nonnegative integers. Otherwise, both x and y must be vectors or factors of the same length. Incomplete cases are removed, vectors are coerced into factors, and the contingency table is computed from these.

Continuity correction is only used in the 2-by-2 case if correct is TRUE.

## Value

A list with class "htest" containing the following components:

|           |                                                                                                       |
|-----------|-------------------------------------------------------------------------------------------------------|
| statistic | the value of McNemar's statistic.                                                                     |
| parameter | the degrees of freedom of the approximate chi-squared distribution of the test statistic.             |
| p.value   | the p-value of the test.                                                                              |
| method    | a character string indicating the type of test performed, and whether continuity correction was used. |
| data.name | a character string giving the name(s) of the data.                                                    |

---

|        |                     |
|--------|---------------------|
| median | <i>Median Value</i> |
|--------|---------------------|

---

## Description

Compute the sample median.

## Usage

```
median(x, na.rm = FALSE, ...)
## Default S3 method:
median(x, na.rm = FALSE, ...)
```

## Arguments

|                    |                                                                                                                          |
|--------------------|--------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>     | an object for which a method has been defined, or a numeric vector containing the values whose median is to be computed. |
| <code>na.rm</code> | a logical value indicating whether NA values should be stripped before the computation proceeds.                         |
| <code>...</code>   | potentially further arguments for methods; not used in the default method.                                               |

## Details

This is a generic function for which methods can be written. However, the default method makes use of `is.na`, `sort` and `mean` from package **base** all of which are generic, and so the default method will work for most classes (e.g., ["Date"](#)) for which a median is a reasonable concept.

## Value

The default method returns a length-one object of the same type as `x`, except when `x` is logical or integer of even length, when the result will be double.

If there are no values or if `na.rm = FALSE` and there are NA values the result is NA of the same type as `x` (or more generally the result of `x[NA_integer_]`).

medpolish

*Median Polish (Robust Two-way Decomposition) of a Matrix*

---

## Description

Fits an additive model (two-way decomposition) using Tukey's *median polish* procedure.

## Usage

```
medpolish(x, eps = 0.01, maxiter = 10, trace.iter = TRUE,
          na.rm = FALSE)
```

## Arguments

|            |                                                                         |
|------------|-------------------------------------------------------------------------|
| x          | a numeric matrix.                                                       |
| eps        | real number greater than 0. A tolerance for convergence: see 'Details'. |
| maxiter    | the maximum number of iterations                                        |
| trace.iter | logical. Should progress in convergence be reported?                    |
| na.rm      | logical. Should missing values be removed?                              |

## Details

The model fitted is additive (constant + rows + columns). The algorithm works by alternately removing the row and column medians, and continues until the proportional reduction in the sum of absolute residuals is less than `eps` or until there have been `maxiter` iterations. The sum of absolute residuals is printed at each iteration of the fitting process, if `trace.iter` is `TRUE`. If `na.rm` is `FALSE` the presence of any NA value in `x` will cause an error, otherwise NA values are ignored.

`medpolish` returns an object of class `medpolish` (see below). There are printing and plotting methods for this class, which are invoked via by the generics [print](#) and [plot](#).

## Value

An object of class `medpolish` with the following named components:

|           |                            |
|-----------|----------------------------|
| overall   | the fitted constant term.  |
| row       | the fitted row effects.    |
| col       | the fitted column effects. |
| residuals | the residuals.             |
| name      | the name of the dataset.   |

---

model.extract

*Extract Components from a Model Frame*

---

## Description

Returns the response, offset, subset, weights or other special components of a model frame passed as optional arguments to [model.frame](#).

## Usage

```
model.extract(frame, component)
model.offset(x)
model.response(data, type = "any")
model.weights(x)
```

## Arguments

|                |                                                                                                                   |
|----------------|-------------------------------------------------------------------------------------------------------------------|
| frame, x, data | a model frame, see <a href="#">model.frame</a> .                                                                  |
| component      | literal character string or name. The name of a component to extract, such as "weights" or "subset".              |
| type           | One of "any", "numeric" or "double". Using either of latter two coerces the result to have storage mode "double". |

## Details

`model.extract` is provided for compatibility with S, which does not have the more specific functions. It is also useful to extract e.g. the `etastart` and `mustart` components of a [glm](#) fit.

`model.extract(m, "offset")` and `model.extract(m, "response")` are equivalent to `model.offset(m)` and `model.response(m)` respectively. `model.offset` sums any terms specified by [offset](#) terms in the formula or by `offset` arguments in the call producing the model frame: it does check that the offset is numeric.

`model.weights` is slightly different from `model.extract(, "weights")` in not naming the vector it returns.

## Value

The specified component of the model frame, usually a vector. `model.response()` now *drops* a possible "Asis" class (stemming from `I(.)`).

`model.offset` returns NULL if no offset was specified.

## See Also

## Examples

```
a <- model.frame(cbind(ncases,ncontrols) ~ agegp + tobgp + alcgp, data = esoph)
model.extract(a, "response")
stopifnot(model.extract(a, "response") == model.response(a))

a <- model.frame(ncases/(ncases+ncontrols) ~ agegp + tobgp + alcgp,
                 data = esoph, weights = ncases+ncontrols)
model.response(a)
(mw <- model.extract(a, "weights"))
stopifnot(identical(unname(mw), model.weights(a)))

a <- model.frame(cbind(ncases,ncontrols) ~ agegp,
                 something = tobgp, data = esoph)
names(a)
stopifnot(model.extract(a, "something") == esoph$tobgp)
```

---

model.frame

*Extracting the Model Frame from a Formula or Fit*

---

## Description

`model.frame` (a generic function) and its methods return a [data.frame](#) with the variables needed to use formula and any ... arguments.

## Usage

```
model.frame(formula, ...)

## Default S3 method:
model.frame(formula, data = NULL,
```

```

subset = NULL, na.action,
drop.unused.levels = FALSE, xlev = NULL, ...)

## S3 method for class 'aovlist'
model.frame(formula, data = NULL, ...)

## S3 method for class 'glm'
model.frame(formula, ...)

## S3 method for class 'lm'
model.frame(formula, ...)

get_all_vars(formula, data, ...)

```

## Arguments

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| formula            | a model <a href="#">formula</a> or <a href="#">terms</a> object or an R object.                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| data               | a data frame, list or environment (or object coercible by <a href="#">as.data.frame</a> to a data frame), containing the variables in formula. Neither a matrix nor an array will be accepted.                                                                                                                                                                                                                                                                                                                             |
| subset             | a specification of the rows/observations to be used: defaults to all. This can be any valid indexing vector (see <a href="#">[.data.frame]</a> for the rows of data, or a (logical) expression using variables in data or if that is not supplied, in formula. (See additional details about how this argument interacts with data-dependent bases under ‘Details’ below.)                                                                                                                                                 |
| na.action          | an optional (name of a) function for treating missing values (NAs). The default is first, any na.action attribute of data, second a na.action setting of <a href="#">options</a> , and third <a href="#">na.fail</a> if that is unset. The ‘factory-fresh’ default is <a href="#">na.omit</a> . Another possible value is NULL.                                                                                                                                                                                            |
| drop.unused.levels | should factors have unused levels dropped? Defaults to FALSE.                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| xlev               | a named list of character vectors giving the full set of levels to be assumed for each factor.                                                                                                                                                                                                                                                                                                                                                                                                                             |
| ...                | for <code>model.frame</code> methods, a mix of further arguments such as <code>data</code> , <code>na.action</code> , <code>subset</code> to pass to the default method. Any additional arguments (such as <code>offset</code> and <code>weights</code> or other named arguments) which reach the default method are used to create further columns in the model frame, with parenthesised names such as <code>"(offset)"</code> .<br>For <code>get_all_vars</code> , further named columns to include in the model frame. |

## Details

Exactly what happens depends on the class and attributes of the object `formula`. If this is an object of fitted-model class such as `"lm"`, the method will either return the saved model frame used when fitting the model (if any, often selected by argument `model = TRUE`) or pass the call used when fitting on to the default method. The default method itself can cope with rather standard model objects such as those of class `"lqs"` from package **MASS** if no other arguments are supplied.

The rest of this section applies only to the default method.

If either `formula` or `data` is already a model frame (a data frame with a `"terms"` attribute) and the other is missing, the model frame is returned. Unless `formula` is a terms object, `as.formula` and

then `terms` is called on it. (If you wish to use the `keep.order` argument of `terms.formula`, pass a `terms` object rather than a formula.)

Row names for the model frame are taken from the `data` argument if present, then from the names of the response in the formula (or `rownames` if it is a matrix), if there is one.

All the variables in `formula`, `subset` and in `...` are looked for first in `data` and then in the environment of `formula` (see the help for `formula()` for further details) and collected into a data frame. Then the subset expression is evaluated, and it is used as a row index to the data frame. Then the `na.action` function is applied to the data frame (and may well add attributes). The levels of any factors in the data frame are adjusted according to the `drop.unused.levels` and `xlev` arguments: if `xlev` specifies a factor and a character variable is found, it is converted to a factor (as from R 2.10.0).

Because variables in the formula are evaluated before rows are dropped based on `subset`, the characteristics of data-dependent bases such as orthogonal polynomials (i.e. from terms using `poly`) or splines will be computed based on the full data set rather than the subsetted one.

Unless `na.action = NULL`, time-series attributes will be removed from the variables found (since they will be wrong if NAs are removed).

Note that *all* the variables in the formula are included in the data frame, even those preceded by `-`.

Only variables whose type is raw, logical, integer, real, complex or character can be included in a model frame: this includes classed variables such as factors (whose underlying type is integer), but excludes lists.

`get_all_vars` returns a `data.frame` containing the variables used in `formula` plus those specified in `...` which are recycled to the number of data frame rows. Unlike `model.frame.default`, it returns the input variables and not those resulting from function calls in `formula`.

## Value

A `data.frame` containing the variables used in `formula` plus those specified in `...`. It will have additional attributes, including `"terms"` for an object of class `"terms"` derived from `formula`, and possibly `"na.action"` giving information on the handling of NAs (which will not be present if no special handling was done, e.g. by `na.pass`).

|--------------|----------------------------------|
| model.matrix | <i>Construct Design Matrices</i> |
|--------------|----------------------------------|

---

## Description

model.matrix creates a design (or model) matrix, e.g., by expanding factors to a set of dummy variables (depending on the contrasts) and expanding interactions similarly.

## Usage

```
model.matrix(object, ...)

## Default S3 method:
model.matrix(object, data = environment(object),
             contrasts.arg = NULL, xlev = NULL, ...)
## S3 method for class 'lm'
model.matrix(object, ...)
```

## Arguments

|               |                                                                                                                                                                                                                                                                                                    |
|---------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| object        | an object of an appropriate class. For the default method, a model <a href="#">formula</a> or a <a href="#">terms</a> object.                                                                                                                                                                      |
| data          | a data frame created with <a href="#">model.frame</a> . If another sort of object, <a href="#">model.frame</a> is called first.                                                                                                                                                                    |
| contrasts.arg | a list, whose entries are values (numeric matrices, <a href="#">functions</a> or character strings naming functions) to be used as replacement values for the <a href="#">contrasts</a> replacement function and whose names are the names of columns of data containing <a href="#">factors</a> . |
| xlev          | to be used as argument of <a href="#">model.frame</a> if data is such that <a href="#">model.frame</a> is called.                                                                                                                                                                                  |
| ...           | further arguments passed to or from other methods.                                                                                                                                                                                                                                                 |

## Details

model.matrix creates a design matrix from the description given in [terms\(object\)](#), using the data in [data](#) which must supply variables with the same names as would be created by a call to [model.frame\(object\)](#) or, more precisely, by evaluating `attr(terms(object), "variables")`. If [data](#) is a data frame, there may be other columns and the order of columns is not important. Any character variables are coerced to factors. After coercion, all the variables used on the right-hand side of the formula must be logical, integer, numeric or factor.

If [contrasts.arg](#) is specified for a factor it overrides the default factor coding for that variable and any "contrasts" attribute set by [C](#) or [contrasts](#). Whereas invalid [contrasts.args](#) have been ignored always, they are warned about since R version 3.6.0.

In an interaction term, the variable whose levels vary fastest is the first one to appear in the formula (and not in the term), so in `~ a + b + b:a` the interaction will have a varying fastest.

By convention, if the response variable also appears on the right-hand side of the formula it is dropped (with a warning), although interactions involving the term are retained.

**Value**

The design matrix for a regression-like model with the specified formula and data.

There is an attribute "assign", an integer vector with an entry for each column in the matrix giving the term in the formula which gave rise to the column. Value 0 corresponds to the intercept (if any), and positive values to terms in the order given by the term.labels attribute of the terms structure corresponding to object.

If there are any factors in terms in the model, there is an attribute "contrasts", a named list with an entry for each factor. This specifies the contrasts that would be used in terms in which the factor is coded by contrasts (in some terms dummy coding may be used), either as a character vector naming a function or as a numeric matrix.

[sparse.model.matrix](#) from package **Matrix** for creating *sparse* model matrices, which may be more efficient in large dimensions.

**Examples**

```
ff <- log(Volume) ~ log(Height) + log(Girth)
utils::str(m <- model.frame(ff, trees))
mat <- model.matrix(ff, m)

dd <- data.frame(a = gl(3,4), b = gl(4,1,12)) # balanced 2-way
options("contrasts") # typically 'treatment' (for unordered factors)
model.matrix(~ a + b, dd)
model.matrix(~ a + b, dd, contrasts.arg = list(a = "contr.sum"))
model.matrix(~ a + b, dd, contrasts.arg = list(a = "contr.sum", b = contr.poly))
m.orth <- model.matrix(~a+b, dd, contrasts.arg = list(a = "contr.helmert"))
crossprod(m.orth) # m.orth is ALMOST orthogonal
# invalid contrasts.. ignored with a warning:
stopifnot(identical(
  model.matrix(~ a + b, dd),
  model.matrix(~ a + b, dd, contrasts.arg = "contr.F00")))
```

---

model.tables

---

*Compute Tables of Results from an aov Model Fit*

---

**Description**

Computes summary tables for model fits, especially complex aov fits.

**Usage**

```
model.tables(x, ...)

## S3 method for class 'aov'
model.tables(x, type = "effects", se = FALSE, cterms, ...)

## S3 method for class 'aovlist'
model.tables(x, type = "effects", se = FALSE, ...)
```

**Arguments**

|                      |                                                                                                                  |
|----------------------|------------------------------------------------------------------------------------------------------------------|
| <code>x</code>       | a model object, usually produced by <code>aov</code>                                                             |
| <code>type</code>    | type of table: currently only "effects" and "means" are implemented. Can be abbreviated.                         |
| <code>se</code>      | should standard errors be computed?                                                                              |
| <code>cterm</code> s | A character vector giving the names of the terms for which tables should be computed. The default is all tables. |
| <code>...</code>     | further arguments passed to or from other methods.                                                               |

**Details**

For type = "effects" give tables of the coefficients for each term, optionally with standard errors.  
 For type = "means" give tables of the mean response for each combinations of levels of the factors in a term.

The "aov" method cannot be applied to components of a "aovlist" fit.

**Value**

An object of class "tables.aov", as list which may contain components

|                     |                                            |
|---------------------|--------------------------------------------|
| <code>tables</code> | A list of tables for each requested term.  |
| <code>n</code>      | The replication information for each term. |
| <code>se</code>     | Standard error information.                |

**Warning**

The implementation is incomplete, and only the simpler cases have been tested thoroughly.  
 Weighted aov fits are not supported.

**See Also**

[aov](#), [proj](#), [replications](#), [TukeyHSD](#), [se.contrast](#)

**Examples**

```
options(contrasts = c("contr.helmert", "contr.treatment"))
npk.aov <- aov(yield ~ block + N*P*K, npk)
model.tables(npk.aov, "means", se = TRUE)

## as a test, not particularly sensible statistically
npk.aovE <- aov(yield ~ N*P*K + Error(block), npk)
model.tables(npk.aovE, se = TRUE)
model.tables(npk.aovE, "means")
```

---

monthplot

---

*Plot a Seasonal or other Subseries from a Time Series*

---

## Description

These functions plot seasonal (or other) subseries of a time series. For each season (or other category), a time series is plotted.

## Usage

```
monthplot(x, ...)

## S3 method for class 'stl'
monthplot(x, labels = NULL, ylab = choice, choice = "seasonal",
          ...)

## S3 method for class 'StructTS'
monthplot(x, labels = NULL, ylab = choice, choice = "sea", ...)

## S3 method for class 'ts'
monthplot(x, labels = NULL, times = time(x), phase = cycle(x),
          ylab = deparse1(substitute(x)), ...)

## Default S3 method:
monthplot(x, labels = 1L:12L,
          ylab = deparse1(substitute(x)),
          times = seq_along(x),
          phase = (times - 1L)%length(labels) + 1L, base = mean,
          axes = TRUE, type = c("l", "h"), box = TRUE,
          add = FALSE,
          col = par("col"), lty = par("lty"), lwd = par("lwd"),
          col.base = col, lty.base = lty, lwd.base = lwd, ...)
```

## Arguments

|        |                                                                                                           |
|--------|-----------------------------------------------------------------------------------------------------------|
| x      | Time series or related object.                                                                            |
| labels | Labels to use for each ‘season’.                                                                          |
| ylab   | y label.                                                                                                  |
| times  | Time of each observation.                                                                                 |
| phase  | Indicator for each ‘season’.                                                                              |
| base   | Function to use for reference line for subseries.                                                         |
| choice | Which series of an stl or StructTS object?                                                                |
| ...    | Arguments to be passed to the default method or graphical parameters.                                     |
| axes   | Should axes be drawn (ignored if add = TRUE)?                                                             |
| type   | Type of plot. The default is to join the points with lines, and "h" is for histogram-like vertical lines. |
| box    | Should a box be drawn (ignored if add = TRUE)?                                                            |
| add    | Should thus just add on an existing plot.                                                                 |

col, lty, lwd      Graphics parameters for the series.  
 col.base, lty.base, lwd.base  
                     Graphics parameters for the segments used for the reference lines.

## Details

These functions extract subseries from a time series and plot them all in one frame. The [ts](#), [stl](#), and [StructTS](#) methods use the internally recorded frequency and start and finish times to set the scale and the seasons. The default method assumes observations come in groups of 12 (though this can be changed).

If the labels are not given but the phase is given, then the labels default to the unique values of the phase. If both are given, then the phase values are assumed to be indices into the labels array, i.e., they should be in the range from 1 to length(labels).

## Value

These functions are executed for their side effect of drawing a seasonal subseries plot on the current graphical window.

mood.test

*Mood Two-Sample Test of Scale***Description**

Performs Mood's two-sample test for a difference in scale parameters.

**Usage**

```
mood.test(x, ...)

## Default S3 method:
mood.test(x, y,
          alternative = c("two.sided", "less", "greater"), ...)

## S3 method for class 'formula'
mood.test(formula, data, subset, na.action, ...)
```

**Arguments**

|                          |                                                                                                                                                                                                                            |
|--------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x, y</code>        | numeric vectors of data values.                                                                                                                                                                                            |
| <code>alternative</code> | indicates the alternative hypothesis and must be one of "two.sided" (default), "greater" or "less" all of which can be abbreviated.                                                                                        |
| <code>formula</code>     | a formula of the form <code>lhs ~ rhs</code> where <code>lhs</code> is a numeric variable giving the data values and <code>rhs</code> a factor with two levels giving the corresponding groups.                            |
| <code>data</code>        | an optional matrix or data frame (or similar: see <a href="#">model.frame</a> ) containing the variables in the formula <code>formula</code> . By default the variables are taken from <code>environment(formula)</code> . |
| <code>subset</code>      | an optional vector specifying a subset of observations to be used.                                                                                                                                                         |
| <code>na.action</code>   | a function which indicates what should happen when the data contain NAs. Defaults to <code>getOption("na.action")</code> .                                                                                                 |
| <code>...</code>         | further arguments to be passed to or from methods.                                                                                                                                                                         |

**Details**

The underlying model is that the two samples are drawn from  $f(x - l)$  and  $f((x - l)/s)/s$ , respectively, where  $l$  is a common location parameter and  $s$  is a scale parameter.

The null hypothesis is  $s = 1$ .

There are more useful tests for this problem.

In the case of ties, the formulation of Mielke (1967) is employed.

**Value**

A list with class "htest" containing the following components:

|                          |                                                                                                    |
|--------------------------|----------------------------------------------------------------------------------------------------|
| <code>statistic</code>   | the value of the test statistic.                                                                   |
| <code>p.value</code>     | the p-value of the test.                                                                           |
| <code>alternative</code> | a character string describing the alternative hypothesis. You can specify just the initial letter. |

method                the character string "Mood two-sample test of scale".  
data.name            a character string giving the names of the data.

|----------|-------------------------------------|
| Multinom | <i>The Multinomial Distribution</i> |
|----------|-------------------------------------|

---

Description

Generate multinomially distributed random number vectors and compute multinomial probabilities.

Usage

```
rmultinom(n, size, prob)  
dmultinom(x, size = NULL, prob, log = FALSE)
```

Arguments

- x                    vector of length  $K$  of integers in  $0: \text{size}$ .
- n                    number of random vectors to draw.
- size                integer, say  $N$ , specifying the total number of objects that are put into  $K$  boxes in the typical multinomial experiment. For `dmultinom`, it defaults to `sum(x)`.
- prob                numeric non-negative vector of length  $K$ , specifying the probability for the  $K$  classes; is internally normalized to sum 1. Infinite and missing values are not allowed.
- log                logical; if TRUE, log probabilities are computed.

## Details

If  $\mathbf{x}$  is a  $K$ -component vector, `dmultinom(x, prob)` is the probability

$$P(X_1 = x_1, \dots, X_K = x_K) = C \times \prod_{j=1}^K \pi_j^{x_j}$$

where  $C$  is the ‘multinomial coefficient’  $C = N!/(x_1! \cdots x_K!)$  and  $N = \sum_{j=1}^K x_j$ .

By definition, each component  $X_j$  is binomially distributed as  $\text{Bin}(\text{size}, \text{prob}[j])$  for  $j = 1, \dots, K$ .

The `rmultinom()` algorithm draws binomials  $X_j$  from  $\text{Bin}(n_j, P_j)$  sequentially, where  $n_1 = N$  ( $N := \text{size}$ ),  $P_1 = \pi_1$  ( $\pi$  is prob scaled to sum 1), and for  $j \geq 2$ , recursively,  $n_j = N - \sum_{k=1}^{j-1} X_k$  and  $P_j = \pi_j / (1 - \sum_{k=1}^{j-1} \pi_k)$ .

## Value

For `rmultinom()`, an integer  $K \times n$  matrix where each column is a random vector generated according to the desired multinomial law, and hence summing to `size`. Whereas the *transposed* result would seem more natural at first, the returned matrix is more efficient because of columnwise storage.

## Note

`dmultinom` is currently *not vectorized* at all and has no C interface (API); this may be amended in the future.

## See Also

[Distributions](#) for standard distributions, including [dbinom](#) which is a special case conceptually.

## Examples

```
rmultinom(10, size = 12, prob = c(0.1,0.2,0.8))

pr <- c(1,3,6,10) # normalization not necessary for generation
rmultinom(10, 20, prob = pr)

## all possible outcomes of Multinom(N = 3, K = 3)
X <- t(as.matrix(expand.grid(0:3, 0:3))); X <- X[, colSums(X) <= 3]
X <- rbind(X, 3:3 - colSums(X)); dimnames(X) <- list(letters[1:3], NULL)
X
round(apply(X, 2, function(x) dmultinom(x, prob = c(1,2,5))), 3)
```

---

na.action

NA Action

---

## Description

Extract information on the NA action used to create an object.

## Usage

```
na.action(object, ...)
```

**Arguments**

object            any object whose NA action is given.  
 ...              further arguments special methods could require.

**Details**

na.action is a generic function, and na.action.default its default method. The latter extracts the "na.action" component of a list if present, otherwise the "na.action" attribute.

When `model.frame` is called, it records any information on NA handling in a "na.action" attribute. Most model-fitting functions return this as a component of their result.

**Value**

Information from the action which was applied to object if NAs were handled specially, or NULL.

**References**

Chambers, J. M. and Hastie, T. J. (1992) *Statistical Models in S*. Wadsworth & Brooks/Cole.

**See Also**

`options("na.action")`, `na.omit`, `na.fail`, also for `na.exclude`, `na.pass`.

**Examples**

```
na.action(na.omit(c(1, NA)))
```

---

|               |                                                   |
|---------------|---------------------------------------------------|
| na.contiguous | <i>Find Longest Contiguous Stretch of non-NAs</i> |
|---------------|---------------------------------------------------|

---

**Description**

Find the longest consecutive stretch of non-missing values in a time series object. (In the event of a tie, the first such stretch.)

**Usage**

```
na.contiguous(object, ...)
```

**Arguments**

object            a univariate or multivariate time series.  
 ...              further arguments passed to or from other methods.

**Value**

A time series without missing values. The class of object will be preserved.

**See Also**

`na.omit` and `na.omit.ts`; `na.fail`

**Examples**

```
na.contiguous(presidents)
```

---

na.fail

*Handle Missing Values in Objects*

---

**Description**

These generic functions are useful for dealing with [NAs](#) in e.g., data frames. `na.fail` returns the object if it does not contain any missing values, and signals an error otherwise. `na.omit` returns the object with incomplete cases removed. `na.pass` returns the object unchanged.

**Usage**

```
na.fail(object, ...)
na.omit(object, ...)
na.exclude(object, ...)
na.pass(object, ...)
```

**Arguments**

|                     |                                                  |
|---------------------|--------------------------------------------------|
| <code>object</code> | an R object, typically a data frame              |
| <code>...</code>    | further arguments special methods could require. |

**Details**

At present these will handle vectors, matrices and data frames comprising vectors and matrices (only).

If `na.omit` removes cases, the row numbers of the cases form the `"na.action"` attribute of the result, of class `"omit"`.

`na.exclude` differs from `na.omit` only in the class of the `"na.action"` attribute of the result, which is `"exclude"`. This gives different behaviour in functions making use of [naresid](#) and [napredict](#): when `na.exclude` is used the residuals and predictions are padded to the correct length by inserting NAs for cases omitted by `na.exclude`.

**References**

Chambers, J. M. and Hastie, T. J. (1992) *Statistical Models in S*. Wadsworth & Brooks/Cole.

**See Also**

[na.action](#); [options](#) with argument `na.action` for setting NA actions; and [lm](#) and [glm](#) for functions using these. [na.contiguous](#) as alternative for time series.

**Examples**

```
DF <- data.frame(x = c(1, 2, 3), y = c(0, 10, NA))
na.omit(DF)
m <- as.matrix(DF)
na.omit(m)
stopifnot(all(na.omit(1:3) == 1:3)) # does not affect objects with no NA's
try(na.fail(DF)) #> Error: missing values in ...

options("na.action")
```

---

|         |                                  |
|---------|----------------------------------|
| naprint | <i>Adjust for Missing Values</i> |
|---------|----------------------------------|

---

**Description**

Use missing value information to report the effects of an `na.action`.

**Usage**

```
naprint(x, ...)
```

**Arguments**

|                  |                                                           |
|------------------|-----------------------------------------------------------|
| <code>x</code>   | An object produced by an <code>na.action</code> function. |
| <code>...</code> | further arguments passed to or from other methods.        |

**Details**

This is a generic function, and the exact information differs by method. `naprint.omit` reports the number of rows omitted: `naprint.default` reports an empty string.

**Value**

A character string providing information on missing values, for example the number.

---

|         |                                  |
|---------|----------------------------------|
| naresid | <i>Adjust for Missing Values</i> |
|---------|----------------------------------|

---

**Description**

Use missing value information to adjust residuals and predictions.

**Usage**

```
naresid(omit, x, ...)
napredict(omit, x, ...)
```

**Arguments**

|                   |                                                                                                                                                                           |
|-------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>omit</code> | an object produced by an <a href="#">na.action</a> function, typically the "na.action" attribute of the result of <a href="#">na.omit</a> or <a href="#">na.exclude</a> . |
| <code>x</code>    | a vector, data frame, or matrix to be adjusted based upon the missing value information.                                                                                  |
| <code>...</code>  | further arguments passed to or from other methods.                                                                                                                        |

**Details**

These are utility functions used to allow [predict](#), [fitted](#) and [residuals](#) methods for modelling functions to compensate for the removal of NAs in the fitting process. They are used by the default, "lm", "glm" and "nls" methods, and by further methods in packages **MASS**, **rpart** and **survival**. Also used for the scores returned by [factanal](#), [prcomp](#) and [princomp](#).

The default methods do nothing. The default method for the `na.exclude` action is to pad the object with NAs in the correct positions to have the same number of rows as the original data frame.

Currently `naresid` and `napredict` are identical, but future methods need not be. `naresid` is used for residuals, and `napredict` for fitted values, predictions and [weights](#).

**Value**

These return a similar object to `x`.

**Note**

In the early 2000s, packages **rpart** and **survival5** contained versions of these functions that had an `na.omit` action equivalent to that now used for `na.exclude`.

---

NegBinomial

---

*The Negative Binomial Distribution*

---

**Description**

Density, distribution function, quantile function and random generation for the negative binomial distribution with parameters `size` and `prob`.

**Usage**

```
dnbinom(x, size, prob, mu, log = FALSE)
pnbinom(q, size, prob, mu, lower.tail = TRUE, log.p = FALSE)
qnbinom(p, size, prob, mu, lower.tail = TRUE, log.p = FALSE)
rnbinom(n, size, prob, mu)
```

**Arguments**

|                |                                                                                                           |
|----------------|-----------------------------------------------------------------------------------------------------------|
| <code>x</code> | vector of (non-negative integer) quantiles.                                                               |
| <code>q</code> | vector of quantiles.                                                                                      |
| <code>p</code> | vector of probabilities.                                                                                  |
| <code>n</code> | number of observations. If <code>length(n) &gt; 1</code> , the length is taken to be the number required. |

|            |                                                                                                                                                                         |
|------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| size       | target for number of successful trials, or dispersion parameter (the shape parameter of the gamma mixing distribution). Must be strictly positive, need not be integer. |
| prob       | probability of success in each trial. $0 < \text{prob} \leq 1$ .                                                                                                        |
| mu         | alternative parametrization via mean: see ‘Details’.                                                                                                                    |
| log, log.p | logical; if TRUE, probabilities p are given as log(p).                                                                                                                  |
| lower.tail | logical; if TRUE (default), probabilities are $P[X \leq x]$ , otherwise, $P[X > x]$ .                                                                                   |

## Details

The negative binomial distribution with  $\text{size} = n$  and  $\text{prob} = p$  has density

$$p(x) = \frac{\Gamma(x + n)}{\Gamma(n)x!} p^n (1 - p)^x$$

for  $x = 0, 1, 2, \dots, n > 0$  and  $0 < p \leq 1$ .

This represents the number of failures which occur in a sequence of Bernoulli trials before a target number of successes is reached. The mean is  $\mu = n(1 - p)/p$  and variance  $n(1 - p)/p^2$ .

A negative binomial distribution can also arise as a mixture of Poisson distributions with mean distributed as a gamma distribution (see [pgamma](#)) with scale parameter  $(1 - \text{prob})/\text{prob}$  and shape parameter  $\text{size}$ . (This definition allows non-integer values of  $\text{size}$ .)

An alternative parametrization (often used in ecology) is by the *mean*  $\mu$  (see above), and  $\text{size}$ , the *dispersion parameter*, where  $\text{prob} = \text{size}/(\text{size} + \mu)$ . The variance is  $\mu + \mu^2/\text{size}$  in this parametrization.

If an element of  $x$  is not integer, the result of `dnbinom` is zero, with a warning.

The case  $\text{size} == 0$  is the distribution concentrated at zero. This is the limiting distribution for  $\text{size}$  approaching zero, even if  $\mu$  rather than  $\text{prob}$  is held constant. Notice though, that the mean of the limit distribution is 0, whatever the value of  $\mu$ .

The quantile is defined as the smallest value  $x$  such that  $F(x) \geq p$ , where  $F$  is the distribution function.

## Value

`dnbinom` gives the density, `pnbinom` gives the distribution function, `qnbinom` gives the quantile function, and `rnbinom` generates random deviates.

Invalid  $\text{size}$  or  $\text{prob}$  will result in return value `NaN`, with a warning.

The length of the result is determined by  $n$  for `rnbinom`, and is the maximum of the lengths of the numerical arguments for the other functions.

The numerical arguments other than  $n$  are recycled to the length of the result. Only the first elements of the logical arguments are used.

`rnbinom` returns a vector of type [integer](#) unless generated values exceed the maximum representable integer when [double](#) values are returned.

## Source

`dnbinom` computes via binomial probabilities, using code contributed by Catherine Loader (see [dbinom](#)).

`pnbinom` uses [pbeta](#).

qnbinom uses the Cornish–Fisher Expansion to include a skewness correction to a normal approximation, followed by a search.

rnbinom uses the derivation as a gamma mixture of Poisson distributions, see

Devroye, L. (1986) *Non-Uniform Random Variate Generation*. Springer-Verlag, New York. Page 480.

[Distributions](#) for standard distributions, including [dbinom](#) for the binomial, [dpois](#) for the Poisson and [dgeom](#) for the geometric distribution, which is a special case of the negative binomial.

### Examples

```
require(graphics)
x <- 0:11
dnbinom(x, size = 1, prob = 1/2) * 2^(1 + x) # == 1
126 / dnbinom(0:8, size = 2, prob = 1/2) #- theoretically integer

## Cumulative ('p') = Sum of discrete prob.s ('d'); Relative error :
summary(1 - cumsum(dnbinom(x, size = 2, prob = 1/2)) /
        pnbinom(x, size = 2, prob = 1/2))

x <- 0:15
size <- (1:20)/4
persp(x, size, dnb <- outer(x, size, function(x,s) dnbinom(x, s, prob = 0.4)),
      xlab = "x", ylab = "s", zlab = "density", theta = 150)
title(tit <- "negative binomial density(x,s, pr = 0.4) vs. x & s")

image (x, size, log10(dnb), main = paste("log [", tit, "]"))
contour(x, size, log10(dnb), add = TRUE)

## Alternative parametrization
x1 <- rnbinom(500, mu = 4, size = 1)
x2 <- rnbinom(500, mu = 4, size = 10)
x3 <- rnbinom(500, mu = 4, size = 100)
h1 <- hist(x1, breaks = 20, plot = FALSE)
h2 <- hist(x2, breaks = h1$breaks, plot = FALSE)
h3 <- hist(x3, breaks = h1$breaks, plot = FALSE)
barplot(rbind(h1$counts, h2$counts, h3$counts),
        beside = TRUE, col = c("red", "blue", "cyan"),
        names.arg = round(h1$breaks[-length(h1$breaks)]))
```

### Description

nextn returns the smallest integer, greater than or equal to n, which can be obtained as a product of powers of the values contained in factors.

nextn() is intended to be used to find a suitable length to zero-pad the argument of [fft](#) so that the transform is computed quickly. The default value for factors ensures this.

**Usage**

```
nextn(n, factors = c(2,3,5))
```

**Arguments**

**n** a vector of integer numbers (of type "integer" *or* "double").

**factors** a vector of positive integer factors (at least 2 and preferably relative prime, see the note).

**Value**

a vector of the same [length](#) as **n**, of type "integer" when the values are small enough (determined before computing them) and "double" otherwise.

**Note**

If the factors in **factors** are *not* relative prime, i.e., have themselves a common factor larger than one, the result may be wrong in the sense that it may not be the *smallest* integer. E.g., `nextn(91, c(2,6))` returns 128 instead of 96 as `nextn(91, c(2,3))` returns.

When the resulting `N <- nextn(. .)` is larger than  $2^{53}$ , a warning with the true 64-bit integer value is signalled, as integers above that range may not be representable in double precision.

If you really need to deal with such large integers, it may be advisable to use package **gmp**.

**See Also**

[convolve](#), [fft](#).

**Examples**

```
nextn(1001) # 1024
table(nextn(599:630))
n <- 1:100 ; plot(n, nextn(n) - n, type = "o", lwd=2, cex=1/2)
```

---

nlm

---

*Non-Linear Minimization*

---

**Description**

This function carries out a minimization of the function **f** using a Newton-type algorithm. See the references for details.

**Usage**

```
nlm(f, p, ..., hessian = FALSE, typsize = rep(1, length(p)),
    fscale = 1, print.level = 0, ndigit = 12, gradtol = 1e-6,
    stepmax = max(1000 * sqrt(sum((p/typsize)^2)), 1000),
    steptol = 1e-6, iterlim = 100, check.analyticals = TRUE)
```

## Arguments

|                                |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|--------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>f</code>                 | the function to be minimized, returning a single numeric value. This should be a function with first argument a vector of the length of <code>p</code> followed by any other arguments specified by the <code>...</code> argument.<br><br>If the function value has an attribute called <code>gradient</code> or both <code>gradient</code> and <code>hessian</code> attributes, these will be used in the calculation of updated parameter values. Otherwise, numerical derivatives are used. <code>deriv</code> returns a function with suitable <code>gradient</code> attribute and optionally a <code>hessian</code> attribute. |
| <code>p</code>                 | starting parameter values for the minimization.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <code>...</code>               | additional arguments to be passed to <code>f</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <code>hessian</code>           | if TRUE, the hessian of <code>f</code> at the minimum is returned.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <code>typsize</code>           | an estimate of the size of each parameter at the minimum.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <code>fscale</code>            | an estimate of the size of <code>f</code> at the minimum.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <code>print.level</code>       | this argument determines the level of printing which is done during the minimization process. The default value of 0 means that no printing occurs, a value of 1 means that initial and final details are printed and a value of 2 means that full tracing information is printed.                                                                                                                                                                                                                                                                                                                                                  |
| <code>ndigit</code>            | the number of significant digits in the function <code>f</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <code>gradtol</code>           | a positive scalar giving the tolerance at which the scaled gradient is considered close enough to zero to terminate the algorithm. The scaled gradient is a measure of the relative change in <code>f</code> in each direction <code>p[i]</code> divided by the relative change in <code>p[i]</code> .                                                                                                                                                                                                                                                                                                                              |
| <code>stepmax</code>           | a positive scalar which gives the maximum allowable scaled step length. <code>stepmax</code> is used to prevent steps which would cause the optimization function to overflow, to prevent the algorithm from leaving the area of interest in parameter space, or to detect divergence in the algorithm. <code>stepmax</code> would be chosen small enough to prevent the first two of these occurrences, but should be larger than any anticipated reasonable step.                                                                                                                                                                 |
| <code>steptol</code>           | A positive scalar providing the minimum allowable relative step length.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <code>iterlim</code>           | a positive integer specifying the maximum number of iterations to be performed before the program is terminated.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <code>check.analyticals</code> | a logical scalar specifying whether the analytic gradients and Hessians, if they are supplied, should be checked against numerical derivatives at the initial parameter values. This can help detect incorrectly formulated gradients or Hessians.                                                                                                                                                                                                                                                                                                                                                                                  |

## Details

Note that arguments after `...` must be matched exactly.

If a gradient or hessian is supplied but evaluates to the wrong mode or length, it will be ignored if `check.analyticals = TRUE` (the default) with a warning. The hessian is not even checked unless the gradient is present and passes the sanity checks.

The C code for the “perturbed” Cholesky, `choldc()` has had a bug in all R versions before 3.4.1.

From the three methods available in the original source, we always use method “1” which is line search.

The functions supplied should always return finite (including not NA and not NaN) values: for the function value itself non-finite values are replaced by the maximum positive value with a warning.

**Value**

A list containing the following components:

|            |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| minimum    | the value of the estimated minimum of $f$ .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| estimate   | the point at which the minimum value of $f$ is obtained.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| gradient   | the gradient at the estimated minimum of $f$ .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| hessian    | the hessian at the estimated minimum of $f$ (if requested).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| code       | an integer indicating why the optimization process terminated. <ol style="list-style-type: none"> <li><b>1:</b> relative gradient is close to zero, current iterate is probably solution.</li> <li><b>2:</b> successive iterates within tolerance, current iterate is probably solution.</li> <li><b>3:</b> last global step failed to locate a point lower than estimate. Either estimate is an approximate local minimum of the function or <code>steptol</code> is too small.</li> <li><b>4:</b> iteration limit exceeded.</li> <li><b>5:</b> maximum step size <code>stepmax</code> exceeded five consecutive times. Either the function is unbounded below, becomes asymptotic to a finite value from above in some direction or <code>stepmax</code> is too small.</li> </ol> |
| iterations | the number of iterations performed.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

For nonlinear regression, [nls](#) may be better.

**Examples**

```
f <- function(x) sum((x-1:length(x))^2)
nlm(f, c(10,10))
nlm(f, c(10,10), print.level = 2)
utils::str(nlm(f, c(5), hessian = TRUE))

f <- function(x, a) sum((x-a)^2)
nlm(f, c(10,10), a = c(3,5))
f <- function(x, a)
{
  res <- sum((x-a)^2)
```

```

      attr(res, "gradient") <- 2*(x-a)
      res
    }
  nlm(f, c(10,10), a = c(3,5))

  ## more examples, including the use of derivatives.
  ## Not run: demo(nlm)

```

nlminb

*Optimization using PORT routines***Description**

Unconstrained and box-constrained optimization using PORT routines.

For historical compatibility.

**Usage**

```
nlminb(start, objective, gradient = NULL, hessian = NULL, ...,
       scale = 1, control = list(), lower = -Inf, upper = Inf)
```

**Arguments**

|                           |                                                                                                                                                                                                                                                                                                                                              |
|---------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>start</code>        | numeric vector, initial values for the parameters to be optimized.                                                                                                                                                                                                                                                                           |
| <code>objective</code>    | Function to be minimized. Must return a scalar value. The first argument to <code>objective</code> is the vector of parameters to be optimized, whose initial values are supplied through <code>start</code> . Further arguments (fixed during the course of the optimization) to <code>objective</code> may be specified as well (see ...). |
| <code>gradient</code>     | Optional function that takes the same arguments as <code>objective</code> and evaluates the gradient of <code>objective</code> at its first argument. Must return a vector as long as <code>start</code> .                                                                                                                                   |
| <code>hessian</code>      | Optional function that takes the same arguments as <code>objective</code> and evaluates the hessian of <code>objective</code> at its first argument. Must return a square matrix of order <code>length(start)</code> . Only the lower triangle is used.                                                                                      |
| <code>...</code>          | Further arguments to be supplied to <code>objective</code> .                                                                                                                                                                                                                                                                                 |
| <code>scale</code>        | See PORT documentation (or leave alone).                                                                                                                                                                                                                                                                                                     |
| <code>control</code>      | A list of control parameters. See below for details.                                                                                                                                                                                                                                                                                         |
| <code>lower, upper</code> | vectors of lower and upper bounds, replicated to be as long as <code>start</code> . If unspecified, all parameters are assumed to be unconstrained.                                                                                                                                                                                          |

**Details**

Any names of `start` are passed on to `objective` and where applicable, `gradient` and `hessian`. The parameter vector will be coerced to double.

If any of the functions returns NA or NaN this is an error for the gradient and Hessian, and such values for function evaluation are replaced by +Inf with a warning.

**Value**

A list with components:

|                          |                                                                                                                               |
|--------------------------|-------------------------------------------------------------------------------------------------------------------------------|
| <code>par</code>         | The best set of parameters found.                                                                                             |
| <code>objective</code>   | The value of objective corresponding to <code>par</code> .                                                                    |
| <code>convergence</code> | An integer code. 0 indicates successful convergence.                                                                          |
| <code>message</code>     | A character string giving any additional information returned by the optimizer, or NULL. For details, see PORT documentation. |
| <code>iterations</code>  | Number of iterations performed.                                                                                               |
| <code>evaluations</code> | Number of objective function and gradient function evaluations                                                                |

**Control parameters**

Possible names in the control list and their default values are:

`eval.max` Maximum number of evaluations of the objective function allowed. Defaults to 200.  
`iter.max` Maximum number of iterations allowed. Defaults to 150.  
`trace` The value of the objective function and the parameters is printed every `trace`'th iteration. Defaults to 0 which indicates no trace information is to be printed.  
`abs.tol` Absolute tolerance. Defaults to 0 so the absolute convergence test is not used. If the objective function is known to be non-negative, the previous default of 1e-20 would be more appropriate.  
`rel.tol` Relative tolerance. Defaults to 1e-10.  
`x.tol` X tolerance. Defaults to 1.5e-8.  
`xf.tol` false convergence tolerance. Defaults to 2.2e-14.  
`step.min`, `step.max` Minimum and maximum step size. Both default to 1..  
`sing.tol` singular convergence tolerance; defaults to `rel.tol`.  
`scale.init` ...  
`diff.g` an estimated bound on the relative error in the objective function value.

```

## Description

Determine the nonlinear (weighted) least-squares estimates of the parameters of a nonlinear model.

## Usage

```
nls(formula, data, start, control, algorithm,
    trace, subset, weights, na.action, model,
    lower, upper, ...)
```

## Arguments

|              |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|--------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| formula      | a nonlinear model <a href="#">formula</a> including variables and parameters. Will be coerced to a formula if necessary.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| data         | an optional data frame in which to evaluate the variables in formula and weights. Can also be a list or an environment, but not a matrix.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| start        | a named list or named numeric vector of starting estimates. When start is missing (and formula is not a self-starting model, see <a href="#">selfStart</a> ), a very cheap guess for start is tried (if algorithm != "plinear").                                                                                                                                                                                                                                                                                                                                                                                               |
| control      | an optional <a href="#">list</a> of control settings. See <a href="#">nls.control</a> for the names of the settable control values and their effect.                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| algorithm    | character string specifying the algorithm to use. The default algorithm is a Gauss-Newton algorithm. Other possible values are "plinear" for the Golub-Pereyra algorithm for partially linear least-squares models and "port" for the 'nl2sol' algorithm from the Port library – see the references. Can be abbreviated.                                                                                                                                                                                                                                                                                                       |
| trace        | logical value indicating if a trace of the iteration progress should be printed. Default is FALSE. If TRUE the residual (weighted) sum-of-squares, the convergence criterion and the parameter values are printed at the conclusion of each iteration. Note that <a href="#">format()</a> is used, so these mostly depend on <a href="#">getOption("digits")</a> . When the "plinear" algorithm is used, the conditional estimates of the linear parameters are printed after the nonlinear parameters. When the "port" algorithm is used the objective function value printed is half the residual (weighted) sum-of-squares. |
| subset       | an optional vector specifying a subset of observations to be used in the fitting process.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| weights      | an optional numeric vector of (fixed) weights. When present, the objective function is weighted least squares.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| na.action    | a function which indicates what should happen when the data contain NAs. The default is set by the na.action setting of <a href="#">options</a> , and is <a href="#">na.fail</a> if that is unset. The 'factory-fresh' default is <a href="#">na.omit</a> . Value <a href="#">na.exclude</a> can be useful.                                                                                                                                                                                                                                                                                                                    |
| model        | logical. If true, the model frame is returned as part of the object. Default is FALSE.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| lower, upper | vectors of lower and upper bounds, replicated to be as long as start. If unspecified, all parameters are assumed to be unconstrained. Bounds can only be used with the "port" algorithm. They are ignored, with a warning, if given for other algorithms.                                                                                                                                                                                                                                                                                                                                                                      |
| ...          | Additional optional arguments. None are used at present.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

## Details

An `nls` object is a type of fitted model object. It has methods for the generic functions `anova`, `coef`, `confint`, `deviance`, `df.residual`, `fitted`, `formula`, `logLik`, `predict`, `print`, `profile`, `residuals`, `summary`, `vcov` and `weights`.

Variables in `formula` (and `weights` if not missing) are looked for first in `data`, then the environment of `formula` and finally along the search path. Functions in `formula` are searched for first in the environment of `formula` and then along the search path.

Arguments `subset` and `na.action` are supported only when all the variables in the `formula` taken from `data` are of the same length: other cases give a warning.

Note that the `anova` method does not check that the models are nested: this cannot easily be done automatically, so use with care.

## Value

A list of

|                                   |                                                                                                                                                                                                                                      |
|-----------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>m</code>                    | an <code>nlsModel</code> object incorporating the model.                                                                                                                                                                             |
| <code>data</code>                 | the expression that was passed to <code>nls</code> as the <code>data</code> argument. The actual data values are present in the <code>environment</code> of the <code>m</code> components, e.g., <code>environment(m\$conv)</code> . |
| <code>call</code>                 | the matched call with several components, notably <code>algorithm</code> .                                                                                                                                                           |
| <code>na.action</code>            | the <code>"na.action"</code> attribute (if any) of the model frame.                                                                                                                                                                  |
| <code>dataClasses</code>          | the <code>"dataClasses"</code> attribute (if any) of the <code>"terms"</code> attribute of the model frame.                                                                                                                          |

## Warning

**The default settings of `nls` generally fail on artificial “zero-residual” data problems.**

The `nls` function uses a relative-offset convergence criterion that compares the numerical imprecision at the current parameter estimates to the residual sum-of-squares. This performs well on data of the form

$$y = f(x, \theta) + \varepsilon$$

(with  $\text{var}(\varepsilon) > 0$ ). It fails to indicate convergence on data of the form

$$y = f(x, \theta)$$

because the criterion amounts to comparing two components of the round-off error. To avoid a zero-divide in computing the convergence testing value, a positive constant `scaleOffset` should be added to the denominator sum-of-squares; it is set in `control`, as in the example below; this does not yet apply to `algorithm = "port"`.

The `algorithm = "port"` code appears unfinished, and does not even check that the starting value is within the bounds. Use with caution, especially where bounds are supplied.

**Note**

Setting `warnOnly = TRUE` in the `control` argument (see [nls.control](#)) returns a non-converged object (since R version 2.5.0) which might be useful for further convergence analysis, *but **not** for inference*.

nls.control

*Control the Iterations in nls*

---

## Description

Allow the user to set some characteristics of the [nls](#) nonlinear least squares algorithm.

## Usage

```

nls.control(maxiter = 50, tol = 1e-05, minFactor = 1/1024,
            printEval = FALSE, warnOnly = FALSE, scaleOffset = 0,
            nDcentral = FALSE)

```

## Arguments

|           |                                                                                                                                                                                                                                                                                                                                                                   |
|-----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| maxiter   | A positive integer specifying the maximum number of iterations allowed.                                                                                                                                                                                                                                                                                           |
| tol       | A positive numeric value specifying the tolerance level for the relative offset convergence criterion.                                                                                                                                                                                                                                                            |
| minFactor | A positive numeric value specifying the minimum step-size factor allowed on any step in the iteration. The increment is calculated with a Gauss-Newton algorithm and successively halved until the residual sum of squares has been decreased or until the step-size factor has been reduced below this limit.                                                    |
| printEval | a logical specifying whether the number of evaluations (steps in the gradient direction taken each iteration) is printed.                                                                                                                                                                                                                                         |
| warnOnly  | a logical specifying whether <a href="#">nls()</a> should return instead of signalling an error in the case of termination before convergence. Termination before convergence happens upon completion of <code>maxiter</code> iterations, in the case of a singular gradient, and in the case that the step-size factor is reduced below <code>minFactor</code> . |

|             |                                                                                                                                                                                                                                                                                                                                                             |
|-------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| scaleOffset | a constant to be added to the denominator of the relative offset convergence criterion calculation to avoid a zero divide in the case where the fit of a model to data is very close. The default value of 0 keeps the legacy behaviour of <code>nls()</code> . A value such as 1 seems to work for problems of reasonable scale with very small residuals. |
| nDcentral   | only when <i>numerical</i> derivatives are used: <code>logical</code> indicating if <i>central</i> differences should be employed, i.e., <code>numericDeriv(*, central=TRUE)</code> be used.                                                                                                                                                                |

**Value**

A `list` with components

maxiter  
tol  
minFactor  
printEval  
warnOnly  
scaleOffset  
nDcentral

with meanings as explained under ‘Arguments’.

**Author(s)**

```

---

NLSstAsymptotic

*Fit the Asymptotic Regression Model*

---

**Description**

Fits the asymptotic regression model, in the form  $b_0 + b_1 \cdot (1 - \exp(-\exp(1rc) \cdot x))$  to the `xy` data. This can be used as a building block in determining starting estimates for more complicated models.

**Usage**

```
NLSstAsymptotic(xy)
```

**Arguments**

xy                      a sortedXyData object

**Value**

A numeric value of length 3 with components labelled `b0`, `b1`, and `lrc`. `b0` is the estimated intercept on the y-axis, `b1` is the estimated difference between the asymptote and the y-intercept, and `lrc` is the estimated logarithm of the rate constant.

**Author(s)**

José Pinheiro and Douglas Bates

**See Also**

**Examples**

```
Lob.329 <- Loblolly[ Loblolly$Seed == "329", ]
print(NLSstAsymptotic(sortedXyData(expression(age),
                                     expression(height),
                                     Lob.329)), digits = 3)
```

---

NLSstClosestX

*Inverse Interpolation*

---

**Description**

Use inverse linear interpolation to approximate the x value at which the function represented by xy is equal to yval.

**Usage**

```
NLSstClosestX(xy, yval)
```

**Arguments**

xy                      a sortedXyData object  
yval                    a numeric value on the y scale

**Value**

A single numeric value on the x scale.

**Author(s)**

José Pinheiro and Douglas Bates

**See Also**

NLSstClosestX(DN.srt, 1.0)
```

---

NLSstLfAsymptote

*Horizontal Asymptote on the Left Side*

---

**Description**

Provide an initial guess at the horizontal asymptote on the left side (i.e., small values of  $x$ ) of the graph of  $y$  versus  $x$  from the `xy` object. Primarily used within `initial` functions for self-starting nonlinear regression models.

**Usage**

```
NLSstLfAsymptote(xy)
```

**Arguments**

`xy`                      a `sortedXyData` object

**Value**

A single numeric value estimating the horizontal asymptote for small  $x$ .

**Author(s)**

José Pinheiro and Douglas Bates

**See Also**

[sortedXyData](#), [NLSstClosestX](#), [NLSstRtAsymptote](#), [selfStart](#)

**Examples**

```

DN.srt <- sortedXyData( expression(log(conc)), expression(density), DNase.2 )
NLSstLfAsymptote( DN.srt )
```

---

|                  |                                               |
|------------------|-----------------------------------------------|
| NLSstRtAsymptote | <i>Horizontal Asymptote on the Right Side</i> |
|------------------|-----------------------------------------------|

---

**Description**

Provide an initial guess at the horizontal asymptote on the right side (i.e., large values of  $x$ ) of the graph of  $y$  versus  $x$  from the `xy` object. Primarily used within initial functions for self-starting nonlinear regression models.

**Usage**

```
NLSstRtAsymptote(xy)
```

**Arguments**

`xy`                      a sortedXyData object

**Value**

A single numeric value estimating the horizontal asymptote for large  $x$ .

|      |                                                      |
|------|------------------------------------------------------|
| nobs | <i>Extract the Number of Observations from a Fit</i> |
|------|------------------------------------------------------|

---

**Description**

Extract the number of ‘observations’ from a model fit. This is principally intended to be used in computing BIC (see [AIC](#)).

**Usage**

```
nobs(object, ...)
```

## Default S3 method:

```
nobs(object, use.fallback = FALSE, ...)
```

Arguments

|                           |                                                                     |
|---------------------------|---------------------------------------------------------------------|
| <code>object</code>       | a fitted model object.                                              |
| <code>use.fallback</code> | logical: should fallback methods be used to try to guess the value? |
| <code>...</code>          | further arguments to be passed to methods.                          |

Details

This is a generic function, with an S4 generic in package **stats4**. There are methods in this package for objects of classes `"lm"`, `"glm"`, `"nls"` and `"logLik"`, as well as a default method (which throws an error, unless `use.fallback = TRUE` when it looks for weights and residuals components – use with care!).

The main usage is in determining the appropriate penalty for BIC, but `nobs` is also used by the stepwise fitting methods `step`, `add1` and `drop1` as a quick check that different fits have been fitted to the same set of data (and not, say, that further rows have been dropped because of NAs in the new predictors).

For `lm`, `glm` and `nls` fits, observations with zero weight are not included.

Value

A single number, normally an integer. Could be NA.

See Also

[AIC](#).

---

|        |                                |
|--------|--------------------------------|
| Normal | <i>The Normal Distribution</i> |
|--------|--------------------------------|

---

Description

Density, distribution function, quantile function and random generation for the normal distribution with mean equal to mean and standard deviation equal to sd.

Usage

```
dnorm(x, mean = 0, sd = 1, log = FALSE)
pnorm(q, mean = 0, sd = 1, lower.tail = TRUE, log.p = FALSE)
qnorm(p, mean = 0, sd = 1, lower.tail = TRUE, log.p = FALSE)
rnorm(n, mean = 0, sd = 1)
```

Arguments

|                         |                                                                                                           |
|-------------------------|-----------------------------------------------------------------------------------------------------------|
| <code>x, q</code>       | vector of quantiles.                                                                                      |
| <code>p</code>          | vector of probabilities.                                                                                  |
| <code>n</code>          | number of observations. If <code>length(n) &gt; 1</code> , the length is taken to be the number required. |
| <code>mean</code>       | vector of means.                                                                                          |
| <code>sd</code>         | vector of standard deviations.                                                                            |
| <code>log, log.p</code> | logical; if TRUE, probabilities p are given as <code>log(p)</code> .                                      |
| <code>lower.tail</code> | logical; if TRUE (default), probabilities are $P[X \leq x]$ otherwise, $P[X > x]$ .                       |

## Details

If mean or sd are not specified they assume the default values of 0 and 1, respectively.

The normal distribution has density

$$f(x) = \frac{1}{\sqrt{2\pi}\sigma} e^{-(x-\mu)^2/2\sigma^2}$$

where  $\mu$  is the mean of the distribution and  $\sigma$  the standard deviation.

## Value

dnorm gives the density, pnorm gives the distribution function, qnorm gives the quantile function, and rnorm generates random deviates.

The length of the result is determined by n for rnorm, and is the maximum of the lengths of the numerical arguments for the other functions.

The numerical arguments other than n are recycled to the length of the result. Only the first elements of the logical arguments are used.

For sd = 0 this gives the limit as sd decreases to 0, a point mass at mu. sd < 0 is an error and returns NaN.

## Source

For pnorm, based on

Cody, W. D. (1993) Algorithm 715: SPECFUN – A portable FORTRAN package of special function routines and test drivers. *ACM Transactions on Mathematical Software* **19**, 22–32.

For qnorm, the code is based on a C translation of

Wichura, M. J. (1988) Algorithm AS 241: The percentage points of the normal distribution. *Applied Statistics*, **37**, 477–484; doi:10.2307/2347330.

which provides precise results up to about 16 digits for log.p=FALSE. For log scale probabilities in the extreme tails, since R version 4.1.0, extensively since 4.3.0, asymptotic expansions are used which have been derived and explored in

Maechler, M. (2022) Asymptotic tail formulas for gaussian quantiles; **DPQ** vignette <https://CRAN.R-project.org/package=DPQ/vignettes/qnorm-asymp.pdf>.

For rnorm, see [RNG](#) for how to select the algorithm and for references to the supplied methods.

## Examples

```
require(graphics)

dnorm(0) == 1/sqrt(2*pi)
dnorm(1) == exp(-1/2)/sqrt(2*pi)
dnorm(1) == 1/sqrt(2*pi*exp(1))

## Using "log = TRUE" for an extended range :
par(mfrow = c(2,1))
plot(function(x) dnorm(x, log = TRUE), -60, 50,
     main = "log { Normal density }")
curve(log(dnorm(x)), add = TRUE, col = "red", lwd = 2)
mtext("dnorm(x, log=TRUE)", adj = 0)
mtext("log(dnorm(x))", col = "red", adj = 1)

plot(function(x) pnorm(x, log.p = TRUE), -50, 10,
     main = "log { Normal Cumulative }")
curve(log(pnorm(x)), add = TRUE, col = "red", lwd = 2)
mtext("pnorm(x, log=TRUE)", adj = 0)
mtext("log(pnorm(x))", col = "red", adj = 1)

## if you want the so-called 'error function'
erf <- function(x) 2 * pnorm(x * sqrt(2)) - 1
## (see Abramowitz and Stegun 29.2.29)
## and the so-called 'complementary error function'
erfc <- function(x) 2 * pnorm(x * sqrt(2), lower = FALSE)
## and the inverses
erfinv <- function(x) qnorm((1 + x)/2)/sqrt(2)
erfcinv <- function(x) qnorm(x/2, lower = FALSE)/sqrt(2)
```

---

numericDeriv

*Evaluate Derivatives Numerically*

---

## Description

numericDeriv numerically evaluates the gradient of an expression.

## Usage

```
numericDeriv(expr, theta, rho = parent.frame(), dir = 1,
             eps = .Machine$double.eps ^ (1/if(central) 3 else 2), central = FALSE)
```

## Arguments

|       |                                                                                                                                                       |
|-------|-------------------------------------------------------------------------------------------------------------------------------------------------------|
| expr  | <a href="#">expression</a> or <a href="#">call</a> to be differentiated. Should evaluate to a <a href="#">numeric</a> vector.                         |
| theta | <a href="#">character</a> vector of names of numeric variables used in expr.                                                                          |
| rho   | <a href="#">environment</a> containing all the variables needed to evaluate expr.                                                                     |
| dir   | numeric vector of directions, typically with values in -1, 1 to use for the finite differences; will be recycled to the length of theta.              |
| eps   | a positive number, to be used as unit step size $h$ for the approximate numerical derivative $(f(x+h) - f(x))/h$ or the central version, see central. |

`central` logical indicating if *central* divided differences should be computed, i.e.,  $(f(x+h) - f(x-h))/2h$ . These are typically more accurate but need more evaluations of  $f()$ .

### Details

This is a front end to the C function `numeric_deriv`, which is described in *Writing R Extensions*.

The numeric variables must be of type `double` and not `integer`.

### Value

The value of `eval(expr, envir = rho)` plus a matrix attribute `"gradient"`. The columns of this matrix are the derivatives of the value with respect to the variables listed in `theta`.

### Author(s)

Saikat DebRoy <saikat@stat.wisc.edu>; tweaks and `eps`, `central` options by R Core Team.

### Examples

```
myenv <- new.env()
myenv$mean <- 0.
myenv$sd <- 1.
myenv$x <- seq(-3., 3., length.out = 31)
nD <- numericDeriv(quote(pnorm(x, mean, sd)), c("mean", "sd"), myenv)
str(nD)

## Visualize :
require(graphics)
matplot(myenv$x, cbind(c(nD), attr(nD, "gradient")), type="l")
abline(h=0, lty=3)
## "gradient" is close to the true derivatives, you don't see any diff.:
curve(-dnorm(x), col=2, lty=3, lwd=2, add=TRUE)
curve(-x*dnorm(x), col=3, lty=3, lwd=2, add=TRUE)
##
# shows 1.609e-8 on most platforms
all.equal(attr(nD, "gradient"),
          with(myenv, cbind(-dnorm(x), -x*dnorm(x))))
```

---

offset

*Include an Offset in a Model Formula*

---

### Description

An offset is a term to be added to a linear predictor, such as in a generalised linear model, with known coefficient 1 rather than an estimated coefficient.

### Usage

```
offset(object)
```

**Arguments**

object                      An offset to be included in a model frame

**Details**

There can be more than one offset in a model formula, but `-` is not supported for offset terms (and is equivalent to `+`).

**Value**

The input value.

**See Also**

[model.offset](#), [model.frame](#).

For examples see [glm](#) and [Insurance](#) in package **MASS**.

---

|             |                                                 |
|-------------|-------------------------------------------------|
| oneway.test | <i>Test for Equal Means in a One-Way Layout</i> |
|-------------|-------------------------------------------------|

---

**Description**

Test whether two or more samples from normal distributions have the same means. The variances are not necessarily assumed to be equal.

**Usage**

```
oneway.test(formula, data, subset, na.action, var.equal = FALSE)
```

**Arguments**

|           |                                                                                                                                                                                                                                                                                                                                                                                      |
|-----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| formula   | a formula of the form <code>lhs ~ rhs</code> where <code>lhs</code> gives the sample values and <code>rhs</code> the corresponding groups.                                                                                                                                                                                                                                           |
| data      | an optional matrix or data frame (or similar: see <a href="#">model.frame</a> ) containing the variables in the formula <code>formula</code> . By default the variables are taken from <code>environment(formula)</code> .                                                                                                                                                           |
| subset    | an optional vector specifying a subset of observations to be used.                                                                                                                                                                                                                                                                                                                   |
| na.action | a function which indicates what should happen when the data contain NAs. Defaults to <code>getOption("na.action")</code> .                                                                                                                                                                                                                                                           |
| var.equal | a logical variable indicating whether to treat the variances in the samples as equal. If <code>TRUE</code> , then a simple F test for the equality of means in a one-way analysis of variance is performed. If <code>FALSE</code> , an approximate method of Welch (1951) is used, which generalizes the commonly known 2-sample Welch test to the case of arbitrarily many samples. |

**Details**

If the right-hand side of the formula contains more than one term, their interaction is taken to form the grouping.

**Value**

A list with class "htest" containing the following components:

|           |                                                                                          |
|-----------|------------------------------------------------------------------------------------------|
| statistic | the value of the test statistic.                                                         |
| parameter | the degrees of freedom of the exact or approximate F distribution of the test statistic. |
| p.value   | the p-value of the test.                                                                 |
| method    | a character string indicating the test performed.                                        |
| data.name | a character string giving the names of the data.                                         |

**Examples**

```
## Not assuming equal variances
oneway.test(extra ~ group, data = sleep)
## Assuming equal variances
oneway.test(extra ~ group, data = sleep, var.equal = TRUE)
## which gives the same result as
anova(lm(extra ~ group, data = sleep))
```

---

optim

*General-purpose Optimization*

---

**Description**

General-purpose optimization based on Nelder–Mead, quasi-Newton and conjugate-gradient algorithms. It includes an option for box-constrained optimization and simulated annealing.

**Usage**

```
optim(par, fn, gr = NULL, ...,
      method = c("Nelder-Mead", "BFGS", "CG", "L-BFGS-B", "SANN",
                  "Brent"),
      lower = -Inf, upper = Inf,
      control = list(), hessian = FALSE)

optimHess(par, fn, gr = NULL, ..., control = list())
```

**Arguments**

|              |                                                                                                                                                                                                                                                                                           |
|--------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| par          | Initial values for the parameters to be optimized over.                                                                                                                                                                                                                                   |
| fn           | A function to be minimized (or maximized), with first argument the vector of parameters over which minimization is to take place. It should return a scalar result.                                                                                                                       |
| gr           | A function to return the gradient for the "BFGS", "CG" and "L-BFGS-B" methods. If it is NULL, a finite-difference approximation will be used.<br>For the "SANN" method it specifies a function to generate a new candidate point. If it is NULL a default Gaussian Markov kernel is used. |
| ...          | Further arguments to be passed to fn and gr.                                                                                                                                                                                                                                              |
| method       | The method to be used. See 'Details'. Can be abbreviated.                                                                                                                                                                                                                                 |
| lower, upper | Bounds on the variables for the "L-BFGS-B" method, or bounds in which to <i>search</i> for method "Brent".                                                                                                                                                                                |
| control      | a <a href="#">list</a> of control parameters. See 'Details'.                                                                                                                                                                                                                              |
| hessian      | Logical. Should a numerically differentiated Hessian matrix be returned?                                                                                                                                                                                                                  |

**Details**

Note that arguments after ... must be matched exactly.

By default `optim` performs minimization, but it will maximize if `control$fnscale` is negative. `optimHess` is an auxiliary function to compute the Hessian at a later stage if `hessian = TRUE` was forgotten.

The default method is an implementation of that of Nelder and Mead (1965), that uses only function values and is robust but relatively slow. It will work reasonably well for non-differentiable functions.

Method "BFGS" is a quasi-Newton method (also known as a variable metric algorithm), specifically that published simultaneously in 1970 by Broyden, Fletcher, Goldfarb and Shanno. This uses function values and gradients to build up a picture of the surface to be optimized.

Method "CG" is a conjugate gradients method based on that by Fletcher and Reeves (1964) (but with the option of Polak–Ribiere or Beale–Sorenson updates). Conjugate gradient methods will generally be more fragile than the BFGS method, but as they do not store a matrix they may be successful in much larger optimization problems.

Method "L-BFGS-B" is that of Byrd et al. (1995) which allows *box constraints*, that is each variable can be given a lower and/or upper bound. The initial value must satisfy the constraints. This uses a limited-memory modification of the BFGS quasi-Newton method. If non-trivial bounds are supplied, this method will be selected, with a warning.

Nocedal and Wright (1999) is a comprehensive reference for the previous three methods.

Method "SANN" is by default a variant of simulated annealing given in Belisle (1992). Simulated-annealing belongs to the class of stochastic global optimization methods. It uses only function values but is relatively slow. It will also work for non-differentiable functions. This implementation uses the Metropolis function for the acceptance probability. By default the next candidate point is generated from a Gaussian Markov kernel with scale proportional to the actual temperature. If a function to generate a new candidate point is given, method "SANN" can also be used to solve combinatorial optimization problems. Temperatures are decreased according to the logarithmic cooling schedule as given in Belisle (1992, p. 890); specifically, the temperature is set to  $\text{temp} / \log(((t-1) \% \% \text{tmax}) * \text{tmax} + \exp(1))$ , where  $t$  is the current iteration step and `temp` and `tmax` are specifiable via `control`, see below. Note that the "SANN" method depends critically on the

settings of the control parameters. It is not a general-purpose method but can be very useful in getting to a good value on a very rough surface.

Method "Brent" is for one-dimensional problems only, using `optimize(<ff>, lower, upper, tol = control$reltol)` where `<ff>` is `function(par) fn(par, ...)/control$fnscale`. It can be useful in cases when `optim()` is used inside other functions where only method can be specified, such as in `mle` from package **stats4**.

Function `fn` can return `NA` or `Inf` if the function cannot be evaluated at the supplied value, but the initial value must have a computable finite value of `fn`. (Except for method "L-BFGS-B" where the values should always be finite.)

`optim` can be used recursively, and for a single parameter as well as many. It also accepts a zero-length `par`, and just evaluates the function with that argument.

The control argument is a list that can supply any of the following components:

**trace** Non-negative integer. If positive, tracing information on the progress of the optimization is produced. Higher values may produce more tracing information: for method "L-BFGS-B" there are six levels of tracing. (To understand exactly what these do see the source code: higher levels give more detail.)

**fnscale** An overall scaling to be applied to the value of `fn` and `gr` during optimization. If negative, turns the problem into a maximization problem. Optimization is performed on `fn(par)/fnscale`.

**parscale** A vector of scaling values for the parameters. Optimization is performed on `par/parscale` and these should be comparable in the sense that a unit change in any element produces about a unit change in the scaled value. Not used (nor needed) for method = "Brent".

**ndeps** A vector of step sizes for the finite-difference approximation to the gradient, on `par/parscale` scale. Defaults to `1e-3`.

**maxit** The maximum number of iterations. Defaults to 100 for the derivative-based methods, and 500 for "Nelder-Mead".

For "SANN" **maxit** gives the total number of function evaluations: there is no other stopping criterion. Defaults to 10000.

**abstol** The absolute convergence tolerance. Only useful for non-negative functions, as a tolerance for reaching zero.

**reltol** Relative convergence tolerance. The algorithm stops if it is unable to reduce the value by a factor of `reltol * (abs(val) + reltol)` at a step. Defaults to `sqrt(.Machine$double.eps)`, typically about `1e-8`.

**alpha, beta, gamma** Scaling parameters for the "Nelder-Mead" method. **alpha** is the reflection factor (default 1.0), **beta** the contraction factor (0.5) and **gamma** the expansion factor (2.0).

**REPORT** The frequency of reports for the "BFGS", "L-BFGS-B" and "SANN" methods if `control$trace` is positive. Defaults to every 10 iterations for "BFGS" and "L-BFGS-B", or every 100 temperatures for "SANN".

**warn.1d.NelderMead** a **logical** indicating if the (default) "Nelder-Mead" method should signal a warning when used for one-dimensional minimization. As the warning is sometimes inappropriate, you can suppress it by setting this option to false.

**type** for the conjugate-gradients method. Takes value 1 for the Fletcher-Reeves update, 2 for Polak-Ribiere and 3 for Beale-Sorenson.

**lmm** is an integer giving the number of BFGS updates retained in the "L-BFGS-B" method, It defaults to 5.

`factr` controls the convergence of the "L-BFGS-B" method. Convergence occurs when the reduction in the objective is within this factor of the machine tolerance. Default is  $1e7$ , that is a tolerance of about  $1e-8$ .

`pgtol` helps control the convergence of the "L-BFGS-B" method. It is a tolerance on the projected gradient in the current search direction. This defaults to zero, when the check is suppressed.

`temp` controls the "SANN" method. It is the starting temperature for the cooling schedule. Defaults to 10.

`tmax` is the number of function evaluations at each temperature for the "SANN" method. Defaults to 10.

Any names given to `par` will be copied to the vectors passed to `fn` and `gr`. Note that no other attributes of `par` are copied over.

The parameter vector passed to `fn` has special semantics and may be shared between calls: the function should not change or copy it.

## Value

For `optim`, a list with components:

|                          |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|--------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>par</code>         | The best set of parameters found.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <code>value</code>       | The value of <code>fn</code> corresponding to <code>par</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <code>counts</code>      | A two-element integer vector giving the number of calls to <code>fn</code> and <code>gr</code> respectively. This excludes those calls needed to compute the Hessian, if requested, and any calls to <code>fn</code> to compute a finite-difference approximation to the gradient.                                                                                                                                                                                                                                                                             |
| <code>convergence</code> | An integer code. 0 indicates successful completion (which is always the case for "SANN" and "Brent"). Possible error codes are <ul style="list-style-type: none"> <li>1 indicates that the iteration limit <code>maxit</code> had been reached.</li> <li>10 indicates degeneracy of the Nelder–Mead simplex.</li> <li>51 indicates a warning from the "L-BFGS-B" method; see component <code>message</code> for further details.</li> <li>52 indicates an error from the "L-BFGS-B" method; see component <code>message</code> for further details.</li> </ul> |
| <code>message</code>     | A character string giving any additional information returned by the optimizer, or NULL.                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <code>hessian</code>     | Only if argument <code>hessian</code> is true. A symmetric matrix giving an estimate of the Hessian at the solution found. Note that this is the Hessian of the unconstrained problem even if the box constraints are active.                                                                                                                                                                                                                                                                                                                                  |

For `optimHess`, the description of the `hessian` component applies.

## Note

`optim` will work with one-dimensional `pars`, but the default method does not work well (and will warn). Method "Brent" uses `optimize` and needs bounds to be available; "BFGS" often works well enough if not.

## Source

The code for methods "Nelder-Mead", "BFGS" and "CG" was based originally on Pascal code in Nash (1990) that was translated by p2c and then hand-optimized. Dr Nash has agreed that the code can be made freely available.

The code for method "L-BFGS-B" is based on Fortran code by Zhu, Byrd, Lu-Chen and Nocedal obtained from Netlib (file 'opt/lbfgs\_bcm.shar': another version is in 'toms/778').

The code for method "SANN" was contributed by A. Trapletti.

```

optimize

*One Dimensional Optimization*

## Description

The function `optimize` searches the interval from lower to upper for a minimum or maximum of the function `f` with respect to its first argument.

`optimise` is an alias for `optimize`.

## Usage

```

optimize(f, interval, ..., lower = min(interval), upper = max(interval),
         maximum = FALSE,
         tol = .Machine$double.eps^0.25)
optimise(f, interval, ..., lower = min(interval), upper = max(interval),
         maximum = FALSE,
         tol = .Machine$double.eps^0.25)

```

## Arguments

|                       |                                                                                                                                                      |
|-----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>f</code>        | the function to be optimized. The function is either minimized or maximized over its first argument depending on the value of <code>maximum</code> . |
| <code>interval</code> | a vector containing the end-points of the interval to be searched for the minimum.                                                                   |
| <code>...</code>      | additional named or unnamed arguments to be passed to <code>f</code> .                                                                               |
| <code>lower</code>    | the lower end point of the interval to be searched.                                                                                                  |
| <code>upper</code>    | the upper end point of the interval to be searched.                                                                                                  |
| <code>maximum</code>  | logical. Should we maximize or minimize (the default)?                                                                                               |
| <code>tol</code>      | the desired accuracy.                                                                                                                                |

## Details

Note that arguments after `...` must be matched exactly.

The method used is a combination of golden section search and successive parabolic interpolation, and was designed for use with continuous functions. Convergence is never much slower than that for a Fibonacci search. If  $f$  has a continuous second derivative which is positive at the minimum (which is not at lower or upper), then convergence is superlinear, and usually of the order of about 1.324.

The function  $f$  is never evaluated at two points closer together than  $\epsilon|x_0| + (tol/3)$ , where  $\epsilon$  is approximately `sqrt(.Machine$double.eps)` and  $x_0$  is the final abscissa `optimize()$minimum`.

If  $f$  is a unimodal function and the computed values of  $f$  are always unimodal when separated by at least  $\epsilon|x| + (tol/3)$ , then  $x_0$  approximates the abscissa of the global minimum of  $f$  on the interval lower, upper with an error less than  $\epsilon|x_0| + tol$ .

If  $f$  is not unimodal, then `optimize()` may approximate a local, but perhaps non-global, minimum to the same accuracy.

The first evaluation of  $f$  is always at  $x_1 = a + (1 - \phi)(b - a)$  where  $(a, b) = (\text{lower}, \text{upper})$  and  $\phi = (\sqrt{5} - 1)/2 = 0.61803..$  is the golden section ratio. Almost always, the second evaluation is at  $x_2 = a + \phi(b - a)$ . Note that a local minimum inside  $[x_1, x_2]$  will be found as solution, even when  $f$  is constant in there, see the last example.

$f$  will be called as  $f(x, \dots)$  for a numeric value of  $x$ .

The argument passed to  $f$  has special semantics and used to be shared between calls. The function should not copy it.

## Value

A list with components `minimum` (or `maximum`) and `objective` which give the location of the minimum (or maximum) and the value of the function at that point.

## Source

A C translation of Fortran code <https://netlib.org/fmm/fmin.f> (author(s) unstated) based on the Algol 60 procedure `localmin` given in the reference.

## References

Brent, R. (1973) *Algorithms for Minimization without Derivatives*. Englewood Cliffs N.J.: Prentice-Hall.

## See Also

## Examples

```
require(graphics)

f <- function (x, a) (x - a)^2
xmin <- optimize(f, c(0, 1), tol = 0.0001, a = 1/3)
xmin

## See where the function is evaluated:
optimize(function(x) x^2*(print(x)-1), lower = 0, upper = 10)
```

```
## "wrong" solution with unlucky interval and piecewise constant f():
f <- function(x) ifelse(x > -1, ifelse(x < 4, exp(-1/abs(x - 1)), 10), 10)
fp <- function(x) { print(x); f(x) }

plot(f, -2,5, ylim = 0:1, col = 2)
optimize(fp, c(-4, 20)) # doesn't see the minimum
optimize(fp, c(-7, 20)) # ok
```

---

order.dendrogram

*Ordering or Labels of the Leaves in a Dendrogram*

---

## Description

These functions return the order (index) or the "label" attribute for the leaves in a dendrogram. These indices can then be used to access the appropriate components of any additional data.

## Usage

```
order.dendrogram(x)

## S3 method for class 'dendrogram'
labels(object, ...)
```

## Arguments

|           |                                                    |
|-----------|----------------------------------------------------|
| x, object | a dendrogram (see <a href="#">as.dendrogram</a> ). |
| ...       | additional arguments                               |

## Details

The indices or labels for the leaves in left to right order are retrieved.

## Value

A vector with length equal to the number of leaves in the dendrogram is returned. From `r <- order.dendrogram()`, each element is the index into the original data (from which the dendrogram was computed).

## Author(s)

R. Gentleman (`order.dendrogram`) and Martin Maechler (`labels.dendrogram`).

## See Also

[reorder](#), [dendrogram](#).

## Examples

```
set.seed(123)
x <- rnorm(10)
hc <- hclust(dist(x))
hc$order
dd <- as.dendrogram(hc)
order.dendrogram(dd) ## the same :
stopifnot(hc$order == order.dendrogram(dd))

d2 <- as.dendrogram(hclust(dist(USArrests)))
labels(d2) ## in this case the same as
stopifnot(identical(labels(d2),
  rownames(USArrests)[order.dendrogram(d2)]))
```

---

p.adjust

Adjust P-values for Multiple Comparisons

---

## Description

Given a set of p-values, returns p-values adjusted using one of several methods.

## Usage

```
p.adjust(p, method = p.adjust.methods, n = length(p))

p.adjust.methods
# c("holm", "hochberg", "hommel", "bonferroni", "BH", "BY",
#   "fdr", "none")
```

## Arguments

|        |                                                                                                                                |
|--------|--------------------------------------------------------------------------------------------------------------------------------|
| p      | numeric vector of p-values (possibly with <a href="#">NAs</a> ). Any other R object is coerced by <a href="#">as.numeric</a> . |
| method | correction method, a <a href="#">character</a> string. Can be abbreviated.                                                     |
| n      | number of comparisons, must be at least length(p); only set this (to non-default) when you know what you are doing!            |

## Details

The adjustment methods include the Bonferroni correction ("bonferroni") in which the p-values are multiplied by the number of comparisons. Less conservative corrections are also included by Holm (1979) ("holm"), Hochberg (1988) ("hochberg"), Hommel (1988) ("hommel"), Benjamini & Hochberg (1995) ("BH" or its alias "fdr"), and Benjamini & Yekutieli (2001) ("BY"), respectively. A pass-through option ("none") is also included. The set of methods are contained in the p.adjust.methods vector for the benefit of methods that need to have the method as an option and pass it on to p.adjust.

The first four methods are designed to give strong control of the family-wise error rate. There seems no reason to use the unmodified Bonferroni correction because it is dominated by Holm's method, which is also valid under arbitrary assumptions.

Hochberg's and Hommel's methods are valid when the hypothesis tests are independent or when they are non-negatively associated (Sarkar, 1998; Sarkar and Chang, 1997). Hommel's method is

more powerful than Hochberg's, but the difference is usually small and the Hochberg p-values are faster to compute.

The "BH" (aka "fdr") and "BY" methods of Benjamini, Hochberg, and Yekutieli control the false discovery rate, the expected proportion of false discoveries amongst the rejected hypotheses. The false discovery rate is a less stringent condition than the family-wise error rate, so these methods are more powerful than the others.

Note that you can set `n` larger than `length(p)` which means the unobserved p-values are assumed to be greater than all the observed p for "bonferroni" and "holm" methods and equal to 1 for the other methods.

## Value

A numeric vector of corrected p-values (of the same length as `p`, with names copied from `p`).

`pairwise.*` functions such as [pairwise.t.test](#).

## Examples

```
require(graphics)

set.seed(123)
x <- rnorm(50, mean = c(rep(0, 25), rep(3, 25)))
p <- 2*pnorm(sort(-abs(x)))

round(p, 3)
round(p.adjust(p), 3)
```

```

round(p.adjust(p, "BH"), 3)

## or all of them at once (dropping the "fdr" alias):
p.adjust.M <- p.adjust.methods[p.adjust.methods != "fdr"]
p.adj <- sapply(p.adjust.M, function(meth) p.adjust(p, meth))
p.adj.60 <- sapply(p.adjust.M, function(meth) p.adjust(p, meth, n = 60))
stopifnot(identical(p.adj[, "none"], p), p.adj <= p.adj.60)
round(p.adj, 3)
## or a bit nicer:
noquote(apply(p.adj, 2, format.pval, digits = 3))

## and a graphic:
matplot(p, p.adj, ylab="p.adjust(p, meth)", type = "l", asp = 1, lty = 1:6,
        main = "P-value adjustments")
legend(0.7, 0.6, p.adjust.M, col = 1:6, lty = 1:6)

## Can work with NA's:
pN <- p; iN <- c(46, 47); pN[iN] <- NA
pN.a <- sapply(p.adjust.M, function(meth) p.adjust(pN, meth))
## The smallest 20 P-values all affected by the NA's :
round((pN.a / p.adj)[1:20, ], 4)

```

---

**Pair**

---

*Construct a Paired-Data Object*

---

**Description**

Combines two vectors into an object of class "Pair".

**Usage**

```
Pair(x, y)
```

**Arguments**

**x** a vector, the 1st element of the pair.  
**y** a vector, the 2nd element of the pair. Should have the same length as x.

**Value**

A 2-column matrix of class "Pair".

**Note**

Mostly designed as part of the formula interface to paired tests.

**See Also**

**Description**

Calculate pairwise comparisons between group levels with corrections for multiple testing

**Usage**

```
pairwise.t.test(x, g, p.adjust.method = p.adjust.methods,
  pool.sd = !paired, paired = FALSE,
  alternative = c("two.sided", "less", "greater"),
  ...)
```

Arguments

|                 |                                                                                                                                          |
|-----------------|------------------------------------------------------------------------------------------------------------------------------------------|
| x               | response vector.                                                                                                                         |
| g               | grouping vector or factor.                                                                                                               |
| p.adjust.method | Method for adjusting p values (see <a href="#">p.adjust</a> ).                                                                           |
| pool.sd         | switch to allow/disallow the use of a pooled SD                                                                                          |
| paired          | a logical indicating whether you want paired t-tests.                                                                                    |
| alternative     | a character string specifying the alternative hypothesis, must be one of "two.sided" (default), "greater" or "less". Can be abbreviated. |
| ...             | additional arguments to pass to t.test.                                                                                                  |

Details

The pool.sd switch calculates a common SD for all groups and uses that for all comparisons (this can be useful if some groups are small). This method does not actually call t.test, so extra arguments are ignored. Pooling does not generalize to paired tests so pool.sd and paired cannot both be TRUE.

Only the lower triangle of the matrix of possible comparisons is being calculated, so setting alternative to anything other than "two.sided" requires that the levels of g are ordered sensibly.

Value

Object of class "pairwise.htest"

See Also

[t.test](#), [p.adjust](#)

Examples

```
attach(airquality)
Month <- factor(Month, labels = month.abb[5:9])
pairwise.t.test(Ozone, Month)
pairwise.t.test(Ozone, Month, p.adjust.method = "bonf")
pairwise.t.test(Ozone, Month, pool.sd = FALSE)
detach()
```

---

|                |                                                   |
|----------------|---------------------------------------------------|
| pairwise.table | <i>Tabulate p values for pairwise comparisons</i> |
|----------------|---------------------------------------------------|

---

Description

Creates table of p values for pairwise comparisons with corrections for multiple testing.

Usage

```
pairwise.table(compare.levels, level.names, p.adjust.method)
```

**Arguments**

`compare.levels` a [function](#) to compute (raw) p value given indices i and j.  
`level.names` names of the group levels  
`p.adjust.method` a character string specifying the method for multiple testing adjustment; almost always one of [p.adjust.methods](#). Can be abbreviated.

**Details**

Functions that do multiple group comparisons create separate `compare.levels` functions (assumed to be symmetrical in i and j) and passes them to this function.

**Value**

Table of p values in lower triangular form.

**See Also**

[pairwise.t.test](#)

---

`pairwise.wilcox.test` *Pairwise Wilcoxon Rank Sum Tests*

---

**Description**

Calculate pairwise comparisons between group levels with corrections for multiple testing.

**Usage**

```
pairwise.wilcox.test(x, g, p.adjust.method = p.adjust.methods,
                    paired = FALSE, ...)
```

**Arguments**

`x` response vector.  
`g` grouping vector or factor.  
`p.adjust.method` method for adjusting p values (see [p.adjust](#)). Can be abbreviated.  
`paired` a logical indicating whether you want a paired test.  
`...` additional arguments to pass to [wilcox.test](#).

**Details**

Extra arguments that are passed on to `wilcox.test` may or may not be sensible in this context. In particular, only the lower triangle of the matrix of possible comparisons is being calculated, so setting alternative to anything other than "two.sided" requires that the levels of g are ordered sensibly.

**Value**

Object of class "pairwise.htest"

**See Also**

[wilcox.test](#), [p.adjust](#)

**Examples**

```
attach(airquality)
Month <- factor(Month, labels = month.abb[5:9])
## These give warnings because of ties :
pairwise.wilcox.test(Ozone, Month)
pairwise.wilcox.test(Ozone, Month, p.adjust.method = "bonf")
detach()
```

---

plot.acf

---

*Plot Autocovariance and Autocorrelation Functions*

---

**Description**

Plot method for objects of class "acf".

**Usage**

```
## S3 method for class 'acf'
plot(x, ci = 0.95, type = "h", xlab = "Lag", ylab = NULL,
      ylim = NULL, main = NULL,
      ci.col = "blue", ci.type = c("white", "ma"),
      max.mfrow = 6, ask = Npgs > 1 && dev.interactive(),
      mar = if(nser > 2) c(3,2,2,0.8) else par("mar"),
      oma = if(nser > 2) c(1,1.2,1,1) else par("oma"),
      mgp = if(nser > 2) c(1.5,0.6,0) else par("mgp"),
      xpd = par("xpd"),
      cex.main = if(nser > 2) 1 else par("cex.main"),
      verbose = getOption("verbose"),
      ...)
```

**Arguments**

|                        |                                                                                                                                                                                       |
|------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>         | an object of class "acf".                                                                                                                                                             |
| <code>ci</code>        | coverage probability for confidence interval. Plotting of the confidence interval is suppressed if <code>ci</code> is zero or negative.                                               |
| <code>type</code>      | the type of plot to be drawn, default to histogram like vertical lines.                                                                                                               |
| <code>xlab</code>      | the x label of the plot.                                                                                                                                                              |
| <code>ylab</code>      | the y label of the plot.                                                                                                                                                              |
| <code>ylim</code>      | numeric of length 2 giving the y limits for the plot.                                                                                                                                 |
| <code>main</code>      | overall title for the plot.                                                                                                                                                           |
| <code>ci.col</code>    | colour to plot the confidence interval lines.                                                                                                                                         |
| <code>ci.type</code>   | should the confidence limits assume a white noise input or for lag $k$ an $MA(k-1)$ input? Can be abbreviated.                                                                        |
| <code>max.mfrow</code> | positive integer; for multivariate <code>x</code> indicating how many rows and columns of plots should be put on one page, using <a href="#">par</a> ( <code>mfrow = c(m,m)</code> ). |

|                              |                                                                                                                                     |
|------------------------------|-------------------------------------------------------------------------------------------------------------------------------------|
| ask                          | logical; if TRUE, the user is asked before a new page is started.                                                                   |
| mar, oma, mgp, xpd, cex.main | graphics parameters as in <a href="#">par</a> (*), by default adjusted to use smaller than default margins for multivariate x only. |
| verbose                      | logical. Should R report extra information on progress?                                                                             |
| ...                          | graphics parameters to be passed to the plotting routines.                                                                          |

**Note**

The confidence interval plotted in `plot.acf` is based on an *uncorrelated* series and should be treated with appropriate caution. Using `ci.type = "ma"` may be less potentially misleading.

**See Also**

[acf](#) which calls `plot.acf` by default.

**Examples**

```
require(graphics)

z4 <- ts(matrix(rnorm(400), 100, 4), start = c(1961, 1), frequency = 12)
z7 <- ts(matrix(rnorm(700), 100, 7), start = c(1961, 1), frequency = 12)
acf(z4)
acf(z7, max.mfrow = 7) # squeeze onto 1 page
acf(z7) # multi-page
```

plot.density

*Plot Method for Kernel Density Estimation***Description**

The plot method for density objects.

**Usage**

```
## S3 method for class 'density'
plot(x, main = NULL, xlab = NULL, ylab = "Density", type = "l",
     zero.line = TRUE, ...)
```

**Arguments**

|                        |                                              |
|------------------------|----------------------------------------------|
| x                      | a "density" object.                          |
| main, xlab, ylab, type | plotting parameters with useful defaults.    |
| ...                    | further plotting parameters.                 |
| zero.line              | logical; if TRUE, add a base line at $y = 0$ |

**Value**

None.

**See Also**

[density.](#)

|                  |                                                |
|------------------|------------------------------------------------|
| plot.HoltWinters | <i>Plot function for "HoltWinters" objects</i> |
|------------------|------------------------------------------------|

---

**Description**

Produces a chart of the original time series along with the fitted values. Optionally, predicted values (and their confidence bounds) can also be plotted.

**Usage**

```
## S3 method for class 'HoltWinters'
plot(x, predicted.values = NA, intervals = TRUE,
     separator = TRUE, col = 1, col.predicted = 2,
     col.intervals = 4, col.separator = 1, lty = 1,
     lty.predicted = 1, lty.intervals = 1, lty.separator = 3,
     ylab = "Observed / Fitted",
     main = "Holt-Winters filtering",
     ylim = NULL, ...)
```

**Arguments**

|                              |                                                                                                                                                         |
|------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------|
| x                            | Object of class "HoltWinters"                                                                                                                           |
| predicted.values             | Predicted values as returned by predict.HoltWinters                                                                                                     |
| intervals                    | If TRUE, the prediction intervals are plotted (default).                                                                                                |
| separator                    | If TRUE, a separating line between fitted and predicted values is plotted (default).                                                                    |
| col, lty                     | Color/line type of original data (default: black solid).                                                                                                |
| col.predicted, lty.predicted | Color/line type of fitted and predicted values (default: red solid).                                                                                    |
| col.intervals, lty.intervals | Color/line type of prediction intervals (default: blue solid).                                                                                          |
| col.separator, lty.separator | Color/line type of observed/predicted values separator (default: black dashed).                                                                         |
| ylab                         | Label of the y-axis.                                                                                                                                    |
| main                         | Main title.                                                                                                                                             |
| ylim                         | Limits of the y-axis. If NULL, the range is chosen such that the plot contains the original series, the fitted values, and the predicted values if any. |
| ...                          | Other graphics parameters.                                                                                                                              |

## Description

The [plot](#) and [lines](#) method for R objects of class [isoreg](#).

## Usage

```
## S3 method for class 'isoreg'
plot(x, plot.type = c("single", "row.wise", "col.wise"),
     main = paste("Isotonic regression", deparse(x$call)),
     main2 = "Cumulative Data and Convex Minorant",
     xlab = "x0", ylab = "x$y",
     par.fit = list(col = "red", cex = 1.5, pch = 13, lwd = 1.5),
     mar = if (both) 0.1 + c(3.5, 2.5, 1, 1) else par("mar"),
     mgp = if (both) c(1.6, 0.7, 0) else par("mgp"),
     grid = length(x$x) < 12, ...)

## S3 method for class 'isoreg'
lines(x, col = "red", lwd = 1.5,
      do.points = FALSE, cex = 1.5, pch = 13, ...)
```

## Arguments

|            |                                                                                                                                                                                               |
|------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| x          | an <a href="#">isoreg</a> object.                                                                                                                                                             |
| plot.type  | character indicating which type of plot is desired. The first (default) only draws the data and the fit, where the others add a plot of the cumulative data and fit. Can be abbreviated.      |
| main       | main title of plot, see <a href="#">title</a> .                                                                                                                                               |
| main2      | title for second (cumulative) plot.                                                                                                                                                           |
| xlab, ylab | x- and y- axis annotation.                                                                                                                                                                    |
| par.fit    | a <a href="#">list</a> of arguments (for <a href="#">points</a> and <a href="#">lines</a> ) for drawing the fit.                                                                              |
| mar, mgp   | graphical parameters, see <a href="#">par</a> , mainly for the case of two plots.                                                                                                             |
| grid       | logical indicating if grid lines should be drawn. If true, <a href="#">grid()</a> is used for the first plot, where as vertical lines are drawn at ‘touching’ points for the cumulative plot. |

do.points        for lines(): logical indicating if the step points should be drawn as well (and as they are drawn in plot()).

col, lwd, cex, pch       graphical arguments for lines(), where cex and pch are only used when do.points is TRUE.

...               further arguments passed to and from methods.

[isoreg](#) for computation of isoreg objects.

### Examples

```
require(graphics)

utils::example(isoreg) # for the examples there

plot(y3, main = "simple plot(.) + lines(<isoreg>")
lines(ir3)

## 'same' plot as above, "proving" that only ranks of 'x' are important
plot(isoreg(2^(1:9), c(1,0,4,3,3,5,4,2,0)), plot.type = "row", log = "x")

plot(ir3, plot.type = "row", ylab = "y3")
plot(isoreg(y3 - 4), plot.type = "r", ylab = "y3 - 4")
plot(ir4, plot.type = "ro", ylab = "y4", xlab = "x = 1:n")

## experiment a bit with these (C-c C-j):
plot(isoreg(sample(9), y3), plot.type = "row")
plot(isoreg(sample(9), y3), plot.type = "col.wise")

plot(ir <- isoreg(sample(10), sample(10, replace = TRUE)),
      plot.type = "r")
```

---

plot.lm

*Plot Diagnostics for an lm Object*

---

### Description

Six plots (selectable by which) are currently available: a plot of residuals against fitted values, a Scale-Location plot of  $\sqrt{|residuals|}$  against fitted values, a Q-Q plot of residuals, a plot of Cook's distances versus row labels, a plot of residuals against leverages, and a plot of Cook's distances against leverage/(1-leverage). By default, the first three and 5 are provided.

### Usage

```
## S3 method for class 'lm'
plot(x, which = c(1,2,3,5),
      caption = list("Residuals vs Fitted", "Q-Q Residuals",
                     "Scale-Location", "Cook's distance",
                     "Residuals vs Leverage",
                     expression("Cook's dist vs Leverage* " * h[ii] / (1 - h[ii]))),
```

```

panel = if(add.smooth) function(x, y, ...)
  panel.smooth(x, y, iter=iter.smooth, ...) else points,
sub.caption = NULL, main = "",
ask = prod(par("mfcol")) < length(which) && dev.interactive(),
...,
id.n = 3, labels.id = names(residuals(x)), cex.id = 0.75,
qqline = TRUE, cook.levels = c(0.5, 1.0),
cook.col = 8, cook.lty = 2, cook.legendChanges = list(),
add.smooth = getOption("add.smooth"),
iter.smooth = if(isGlm) 0 else 3,
label.pos = c(4,2),
cex.caption = 1, cex.oma.main = 1.25
, extend.ylim.f = 0.08
)

```

## Arguments

|                    |                                                                                                                                                                                                                                                                                                                                                                        |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| x                  | lm object, typically result of <a href="#">lm</a> or <a href="#">glm</a> .                                                                                                                                                                                                                                                                                             |
| which              | a subset of the numbers 1:6, by default 1:3, 5, referring to <ol style="list-style-type: none"> <li>1. "Residuals vs Fitted", aka ‘Tukey-Anscombe’ plot</li> <li>2. "Residual Q-Q" plot</li> <li>3. "Scale-Location"</li> <li>4. "Cook’s distance"</li> <li>5. "Residuals vs Leverage"</li> <li>6. "Cook’s dist vs Lev./(1-Lev.)"</li> </ol> See also ‘Details’ below. |
| caption            | captions to appear above the plots; <a href="#">character</a> vector or <a href="#">list</a> of valid graphics annotations, see <a href="#">as.graphicsAnnot</a> , of length 6, the j-th entry corresponding to which[j], see also the default vector in ‘Usage’. Can be set to "" or NA to suppress all captions.                                                     |
| panel              | panel function. The useful alternative to <a href="#">points</a> , <a href="#">panel.smooth</a> can be chosen by add.smooth = TRUE.                                                                                                                                                                                                                                    |
| sub.caption        | common title—above the figures if there are more than one; used as sub(s. <a href="#">title</a> ) otherwise. If NULL, as by default, a possible abbreviated version of <code>deparse(x\$call)</code> is used.                                                                                                                                                          |
| main               | title to each plot—in addition to caption.                                                                                                                                                                                                                                                                                                                             |
| ask                | logical; if TRUE, the user is <i>asked</i> before each plot, see <a href="#">par</a> (ask=.).                                                                                                                                                                                                                                                                          |
| ...                | other parameters to be passed through to plotting functions.                                                                                                                                                                                                                                                                                                           |
| id.n               | number of points to be labelled in each plot, starting with the most extreme.                                                                                                                                                                                                                                                                                          |
| labels.id          | vector of labels, from which the labels for extreme points will be chosen. NULL uses observation numbers.                                                                                                                                                                                                                                                              |
| cex.id             | magnification of point labels.                                                                                                                                                                                                                                                                                                                                         |
| qqline             | logical indicating if a <a href="#">qqline</a> () should be added to the normal Q-Q plot.                                                                                                                                                                                                                                                                              |
| cook.levels        | levels of Cook’s distance at which to draw contours.                                                                                                                                                                                                                                                                                                                   |
| cook.col, cook.lty | color and line type to use for these contour lines.                                                                                                                                                                                                                                                                                                                    |

|                                 |                                                                                                                                                                                                                                                                                                                                                        |
|---------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>cook.legendChanges</code> | a <a href="#">list</a> (or NULL to suppress the call) of arguments to <a href="#">legend</a> which should be <i>modified</i> from (or added to) the <code>plot.lm()</code> default <code>list(x = "bottomleft", legend = "Cook's distance", lty = cook.lty, col = cook.col, text.col = cook.col, bty = "n", x.intersp = 1/4, y.intersp = 1/8)</code> . |
| <code>add.smooth</code>         | logical indicating if a smoother should be added to most plots; see also panel above.                                                                                                                                                                                                                                                                  |
| <code>iter.smooth</code>        | the number of robustness iterations, the argument <code>iter</code> in <a href="#">panel.smooth()</a> ; the default uses no such iterations for <a href="#">glm</a> fits which is particularly desirable for the (predominant) case of binary observations, but also for other models where the response distribution can be highly skewed.            |
| <code>label.pos</code>          | positioning of labels, for the left half and right half of the graph respectively, for plots 1-3, 5, 6.                                                                                                                                                                                                                                                |
| <code>cex.caption</code>        | controls the size of caption.                                                                                                                                                                                                                                                                                                                          |
| <code>cex.oma.main</code>       | controls the size of the sub.caption only if that is <i>above</i> the figures when there is more than one.                                                                                                                                                                                                                                             |
| <code>extend.ylim.f</code>      | a numeric vector of length 1 or 2, to be used in <code>ylim &lt;- extendrange(r=ylim, f = *)</code> for plots 1 and 5 when <code>id.n</code> is non-empty.                                                                                                                                                                                             |

## Details

`sub.caption`—by default the function call—is shown as a subtitle (under the x-axis title) on each plot when plots are on separate pages, or as a subtitle in the outer margin (if any) when there are multiple plots per page.

The ‘Scale-Location’ plot (`which=3`), also called ‘Spread-Location’ or ‘S-L’ plot, takes the square root of the absolute residuals in order to diminish skewness ( $\sqrt{|E|}$  is much less skewed than  $|E|$  for Gaussian zero-mean  $E$ ).

The ‘S-L’, the Q-Q, and the Residual-Leverage (`which=5`) plot use *standardized* residuals which have identical variance (under the hypothesis). They are given as  $R_i/(s \times \sqrt{1 - h_{ii}})$  where the ‘*leverages*’  $h_{ii}$  are the diagonal entries of the hat matrix, [influence\(\)](#)\$hat (see also [hat](#)), and where the Residual-Leverage plot uses the standardized Pearson residuals (`residuals.glm(type = "pearson")`) for  $R[i]$ .

The Residual-Leverage plot (`which=5`) shows contours of equal Cook’s distance, for values of `cook.levels` (by default 0.5 and 1) and omits cases with leverage one with a warning. If the leverages are constant (as is typically the case in a balanced [aov](#) situation) the plot uses factor level combinations instead of the leverages for the x-axis. (The factor levels are ordered by mean fitted value.)

In the Cook’s distance vs leverage/(1-leverage) (= “leverage\*”) plot (`which=6`), contours of standardized residuals ([rstandard\(\)](#)) that are equal in magnitude are lines through the origin. These lines are labelled with the magnitudes. The x-axis is labeled with the (non equidistant) leverages  $h_{ii}$ .

For the `glm` case, the Q-Q plot is based on the absolute value of the standardized deviance residuals. When the saddlepoint approximation applies, these have an approximate half-normal distribution. The saddlepoint approximation is exact for the normal and inverse Gaussian family, and holds approximately for the Gamma family with small dispersion (large shape) and for the Poisson and binomial families with large counts (Dunn and Smyth 2018).

## Description

Plot the ridge functions for a projection pursuit regression ([ppr](#)) fit.

## Usage

```

## S3 method for class 'ppr'
plot(x, ask, type = "o", cex = 1/2,
     main = quote(bquote(
       "term"[(i)]*"": " ~ ~ hat(beta[(i)]] == .(bet.i))),
     xlab = quote(bquote(bold(alpha)[(i)]^T * bold(x))),
     ylab = "", ...)

```

## Arguments

|                  |                                                                                                                                              |
|------------------|----------------------------------------------------------------------------------------------------------------------------------------------|
| x                | an R object of class "ppr" as produced by a call to ppr.                                                                                     |
| ask              | the graphics parameter ask: see <a href="#">par</a> for details. If set to TRUE will ask between the plot of each cross-section.             |
| type             | the type of line (see <a href="#">plot.default</a> ) to draw.                                                                                |
| cex              | plot symbol expansion factor ( <i>relative</i> to <a href="#">par</a> ("cex")).                                                              |
| main, xlab, ylab | axis annotations, see also <a href="#">title</a> . Can be an expression (depending on i and bet.i), as by default which will be eval()uated. |
| ...              | further graphical parameters, passed to <a href="#">plot()</a> .                                                                             |

## Value

None

## Side Effects

A series of plots are drawn on the current graphical device, one for each term in the fit.

## See Also

## Examples

```
require(graphics)

rock1 <- within(rock, { area1 <- area/10000; peri1 <- peri/10000 })
par(mfrow = c(3,2)) # maybe: , pty = "s"
rock.ppr <- ppr(log(perm) ~ area1 + peri1 + shape,
               data = rock1, nterms = 2, max.terms = 5)
plot(rock.ppr, main = "ppr(log(perm)~ ., nterms=2, max.terms=5)")
plot(update(rock.ppr, bass = 5), main = "update(..., bass = 5)")
plot(update(rock.ppr, sm.method = "gcv", gcvpen = 2),
     main = "update(..., sm.method=\"gcv\", gcvpen=2)")
```

plot.profile

*Plotting Functions for 'profile' Objects*

## Description

[plot](#) and [pairs](#) methods for objects of class "profile".

## Usage

```
## S3 method for class 'profile'
plot(x, ...)
## S3 method for class 'profile'
pairs(x, colours = 2:3, which = names(x), ...)
```

## Arguments

|         |                                                                             |
|---------|-----------------------------------------------------------------------------|
| x       | an object inheriting from class "profile".                                  |
| colours | colours to be used for the mean curves conditional on x and y respectively. |
| which   | names or number of parameters in pairs plot                                 |
| ...     | arguments passed to or from other methods.                                  |

## Details

This is the main plot method for objects created by [profile.glm](#). It can also be called on objects created by [profile.nls](#), but they have a specific method, [plot.profile.nls](#).

The [pairs](#) method shows, for each pair of parameters x and y, two curves intersecting at the maximum likelihood estimate, which give the loci of the points at which the tangents to the contours of the bivariate profile likelihood become vertical and horizontal, respectively. In the case of an exactly bivariate normal profile likelihood, these two curves would be straight lines giving the conditional means of y|x and x|y, and the contours would be exactly elliptical. The [which](#) argument allows you to select a subset of parameters; the default corresponds to the set of parameters that have been profiled.

## Author(s)

Originally, D. M. Bates and W. N. Venables for S (in 1996). Taken from **MASS** where these functions were re-written by B. D. Ripley for R (by 1998).

**See Also**

[profile.glm](#), [profile.nls](#).

**Examples**

```
## see ?profile.glm for another example using glm fits.

## a version of example(profile.nls) from R >= 2.8.0
fm1 <- nls(demand ~ SSasymptOrig(Time, A, lrc), data = BOD)
pr1 <- profile(fm1, alphamax = 0.1)
stats::plot.profile(pr1) ## override dispatch to plot.profile.nls
pairs(pr1) # a little odd since the parameters are highly correlated

## an example from ?nls
x <- -(1:100)/10
y <- 100 + 10 * exp(x / 2) + rnorm(x)/10
nlmod <- nls(y ~ Const + A * exp(B * x), start=list(Const=100, A=10, B=1))
pairs(profile(nlmod))

## example from Dobson (1990) (see ?glm)
counts <- c(18,17,15,20,10,20,25,13,12)
outcome <- gl(3,1,9)
treatment <- gl(3,3)
## this example is only formally a Poisson model. It is really a
## comparison of 3 multinomials. Only the interaction parameters are of
## interest.
glm.D93i <- glm(counts ~ outcome * treatment, family = poisson())
pr1 <- profile(glm.D93i)
pr2 <- profile(glm.D93i, which=6:9)
plot(pr1)
plot(pr2)
pairs(pr1)
pairs(pr2)
```

---

plot.profile.nls

*Plot a profile.nls Object*

---

**Description**

Displays a series of plots of the profile t function and interpolated confidence intervals for the parameters in a nonlinear regression model that has been fit with `nls` and profiled with `profile.nls`.

**Usage**

```
## S3 method for class 'profile.nls'
plot(x, levels, conf = c(99, 95, 90, 80, 50)/100,
     absVal = TRUE, ylab = NULL, lty = 2, ...)
```

**Arguments**

|                     |                                                                                                                                                                        |
|---------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>      | an object of class "profile.nls"                                                                                                                                       |
| <code>levels</code> | levels, on the scale of the absolute value of a t statistic, at which to interpolate intervals. Usually <code>conf</code> is used instead of giving levels explicitly. |

|           |                                                                                                                                                                          |
|-----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| conf      | a numeric vector of confidence levels for profile-based confidence intervals on the parameters. Defaults to <code>c(0.99, 0.95, 0.90, 0.80, 0.50)</code> .               |
| absVal    | a logical value indicating whether or not the plots should be on the scale of the absolute value of the profile <code>t</code> . Defaults to <code>TRUE</code> .         |
| lty       | the line type to be used for axis and dropped lines.                                                                                                                     |
| ylab, ... | other arguments to the <code>plot.default</code> function can be passed here (but not <code>xlab</code> , <code>xlim</code> , <code>ylim</code> nor <code>type</code> ). |

## Details

The plots are produced in a set of hard-coded colours, but as these are coded by number their effect can be changed by setting the `palette`. Colour 1 is used for the axes and 4 for the profile itself. Colours 3 and 6 are used for the axis line at zero and the horizontal/vertical lines dropping to the axes.

plot.spec

*Plotting Spectral Densities***Description**

Plotting method for objects of class "spec". For multivariate time series it plots the marginal spectra of the series or pairs of plots of the coherency and phase of the cross-spectra.

**Usage**

```
## S3 method for class 'spec'
plot(x, add = FALSE, ci = 0.95, log = c("yes", "dB", "no"),
     xlab = "frequency", ylab = NULL, type = "l",
     ci.col = "blue", ci.lty = 3,
     main = NULL, sub = NULL,
     plot.type = c("marginal", "coherency", "phase"),
     ...)

plot.spec.phase(x, ci = 0.95,
               xlab = "frequency", ylab = "phase",
               ylim = c(-pi, pi), type = "l",
               main = NULL, ci.col = "blue", ci.lty = 3, ...)

plot.spec.coherency(x, ci = 0.95,
                   xlab = "frequency",
                   ylab = "squared coherency",
                   ylim = c(0, 1), type = "l",
                   main = NULL, ci.col = "blue", ci.lty = 3, ...)
```

**Arguments**

|        |                                                                                                                                                                                                                                                               |
|--------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| x      | an object of class "spec".                                                                                                                                                                                                                                    |
| add    | logical. If TRUE, add to already existing plot. Only valid for plot.type = "marginal".                                                                                                                                                                        |
| ci     | coverage probability for confidence interval. Plotting of the confidence bar/limits is omitted unless ci is strictly positive.                                                                                                                                |
| log    | If "dB", plot on log10 (decibel) scale, otherwise use conventional log scale or linear scale. Logical values are also accepted. The default is "yes" unless options(ts.S.compat = TRUE) has been set, when it is "dB". Only valid for plot.type = "marginal". |
| xlab   | the x label of the plot.                                                                                                                                                                                                                                      |
| ylab   | the y label of the plot. If missing a suitable label will be constructed.                                                                                                                                                                                     |
| type   | the type of plot to be drawn, defaults to lines.                                                                                                                                                                                                              |
| ci.col | colour for plotting confidence bar or confidence intervals for coherency and phase.                                                                                                                                                                           |
| ci.lty | line type for confidence intervals for coherency and phase.                                                                                                                                                                                                   |
| main   | overall title for the plot. If missing, a suitable title is constructed.                                                                                                                                                                                      |

|                        |                                                                                                                                  |
|------------------------|----------------------------------------------------------------------------------------------------------------------------------|
| sub                    | a subtitle for the plot. Only used for <code>plot.type = "marginal"</code> . If missing, a description of the smoothing is used. |
| <code>plot.type</code> | For multivariate time series, the type of plot required. Only the first character is needed.                                     |
| <code>ylim, ...</code> | Graphical parameters.                                                                                                            |

| plot.stepfun | <i>Plot Step Functions</i> |
|--------------|----------------------------|

---

**Description**

Method of the generic [plot](#) for [stepfun](#) objects and utility for plotting piecewise constant functions.

**Usage**

```
## S3 method for class 'stepfun'
plot(x, xval, xlim, ylim = range(c(y, Fn.kn)),
      xlab = "x", ylab = "f(x)", main = NULL,
      add = FALSE, verticals = TRUE, do.points = (n < 1000),
      pch = par("pch"), col = par("col"),
      col.points = col, cex.points = par("cex"),
      col.hor = col, col.vert = col,
      lty = par("lty"), lwd = par("lwd"), ...)

## S3 method for class 'stepfun'
lines(x, ...)
```

**Arguments**

|            |                                                                                                                      |
|------------|----------------------------------------------------------------------------------------------------------------------|
| x          | an R object inheriting from "stepfun".                                                                               |
| xval       | numeric vector of abscissa values at which to evaluate x. Defaults to <a href="#">knots(x)</a> restricted to xlim.   |
| xlim, ylim | limits for the plot region: see <a href="#">plot.window</a> . Both have sensible defaults if omitted.                |
| xlab, ylab | labels for x and y axis.                                                                                             |
| main       | main title.                                                                                                          |
| add        | logical; if TRUE only <i>add</i> to an existing plot.                                                                |
| verticals  | logical; if TRUE, draw vertical lines at steps.                                                                      |
| do.points  | logical; if TRUE, also draw points at the (xlim restricted) knot locations. Default is true, for sample size < 1000. |
| pch        | character; point character if do.points.                                                                             |
| col        | default color of all points and lines.                                                                               |
| col.points | character or integer code; color of points if do.points.                                                             |

|            |                                                                                   |
|------------|-----------------------------------------------------------------------------------|
| cex.points | numeric; character expansion factor if do.points.                                 |
| col.hor    | color of horizontal lines.                                                        |
| col.vert   | color of vertical lines.                                                          |
| lty, lwd   | line type and thickness for all lines.                                            |
| ...        | further arguments of <code>plot(.)</code> , or if(add) <code>segments(.)</code> . |

### Value

A list with two components

|   |                                                        |
|---|--------------------------------------------------------|
| t | abscissa (x) values, including the two outermost ones. |
| y | y values 'in between' the t[[]].                       |

### Examples

```
require(graphics)

y0 <- c(1,2,4,3)
sfun0 <- stepfun(1:3, y0, f = 0)
sfun.2 <- stepfun(1:3, y0, f = .2)
sfun1 <- stepfun(1:3, y0, right = TRUE)

tt <- seq(0, 3, by = 0.1)
op <- par(mfrow = c(2,2))
plot(sfun0); plot(sfun0, xval = tt, add = TRUE, col.hor = "bisque")
plot(sfun.2); plot(sfun.2, xval = tt, add = TRUE, col = "orange") # all colors
plot(sfun1); lines(sfun1, xval = tt, col.hor = "coral")
##-- This is revealing :
plot(sfun0, verticals = FALSE,
     main = "stepfun(x, y0, f=f) for f = 0, .2, 1")
for(i in 1:3)
  lines(list(sfun0, sfun.2, stepfun(1:3, y0, f = 1))[[i]], col = i)
legend(2.5, 1.9, paste("f =", c(0, 0.2, 1)), col = 1:3, lty = 1, y.intersp = 1)
par(op)

# Extend and/or restrict 'viewport':
plot(sfun0, xlim = c(0,5), ylim = c(0, 3.5),
     main = "plot(stepfun(*), xlim= . , ylim = .)")

##-- this works too (automatic call to ecdf(.)):
plot.stepfun(rt(50, df = 3), col.vert = "gray20")
```

plot.ts

*Plotting Time-Series Objects***Description**

Plotting method for objects inheriting from class "ts".

**Usage**

```
## S3 method for class 'ts'
plot(x, y = NULL, plot.type = c("multiple", "single"),
      xy.labels, xy.lines, panel = lines, nc, yax.flip = FALSE,
      mar.multi = c(0, 5.1, 0, if(yax.flip) 5.1 else 2.1),
      oma.multi = c(6, 0, 5, 0), axes = TRUE, ...)

## S3 method for class 'ts'
lines(x, ...)
```

**Arguments**

|                                   |                                                                                                                                                                                                                                                                   |
|-----------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x, y</code>                 | time series objects, usually inheriting from class "ts".                                                                                                                                                                                                          |
| <code>plot.type</code>            | for multivariate time series, should the series be plotted separately (with a common time axis) or on a single plot? Can be abbreviated.                                                                                                                          |
| <code>xy.labels</code>            | logical, indicating if <code>text()</code> labels should be used for an x-y plot, or character, supplying a vector of labels to be used. The default is to label for up to 150 points, and not for more.                                                          |
| <code>xy.lines</code>             | logical, indicating if <code>lines</code> should be drawn for an x-y plot. Defaults to the value of <code>xy.labels</code> if that is logical, otherwise to TRUE.                                                                                                 |
| <code>panel</code>                | a function( <code>x</code> , <code>col</code> , <code>bg</code> , <code>pch</code> , <code>type</code> , ...) which gives the action to be carried out in each panel of the display for <code>plot.type = "multiple"</code> . The default is <code>lines</code> . |
| <code>nc</code>                   | the number of columns to use when <code>type = "multiple"</code> . Defaults to 1 for up to 4 series, otherwise to 2.                                                                                                                                              |
| <code>yax.flip</code>             | logical indicating if the y-axis (ticks and numbering) should flip from side 2 (left) to 4 (right) from series to series when <code>type = "multiple"</code> .                                                                                                    |
| <code>mar.multi, oma.multi</code> | the (default) <code>par</code> settings for <code>plot.type = "multiple"</code> . Modify with care!                                                                                                                                                               |
| <code>axes</code>                 | logical indicating if x- and y- axes should be drawn.                                                                                                                                                                                                             |
| <code>...</code>                  | additional graphical arguments, see <code>plot</code> , <code>plot.default</code> and <code>par</code> .                                                                                                                                                          |

**Details**

If `y` is missing, this function creates a time series plot, for multivariate series of one of two kinds depending on `plot.type`.

If `y` is present, both `x` and `y` must be univariate, and a scatter plot  $y \sim x$  will be drawn, enhanced by using `text` if `xy.labels` is TRUE or character, and `lines` if `xy.lines` is TRUE.

**See Also**

[ts](#) for basic time series construction and access functionality.

**Examples**

```
require(graphics)

## Multivariate
z <- ts(matrix(rt(200 * 8, df = 3), 200, 8),
          start = c(1961, 1), frequency = 12)
plot(z, yax.flip = TRUE)
plot(z, axes = FALSE, ann = FALSE, frame.plot = TRUE,
      mar.multi = c(0,0,0,0), oma.multi = c(1,1,5,1))
title("plot(ts(..), axes=FALSE, ann=FALSE, frame.plot=TRUE, mar..., oma...)")

z <- window(z[,1:3], end = c(1969,12))
plot(z, type = "b")      # multiple
plot(z, plot.type = "single", lty = 1:3, col = 4:2)

## A phase plot:
plot(nhtemp, lag(nhtemp, 1), cex = .8, col = "blue",
     main = "Lag plot of New Haven temperatures")

## xy.lines and xy.labels are FALSE for large series:
plot(lag(sunspots, 1), sunspots, pch = ".")

SMI <- EuStockMarkets[, "SMI"]
plot(lag(SMI, 1), SMI, pch = ".")
plot(lag(SMI, 20), SMI, pch = ".", log = "xy",
     main = "4 weeks lagged SMI stocks -- log scale", xy.lines = TRUE)
```

---

Poisson

*The Poisson Distribution*

---

**Description**

Density, distribution function, quantile function and random generation for the Poisson distribution with parameter  $\lambda$ .

**Usage**

```
dpois(x, lambda, log = FALSE)
ppois(q, lambda, lower.tail = TRUE, log.p = FALSE)
qpois(p, lambda, lower.tail = TRUE, log.p = FALSE)
rpois(n, lambda)
```

**Arguments**

|   |                                             |
|---|---------------------------------------------|
| x | vector of (non-negative integer) quantiles. |
| q | vector of quantiles.                        |
| p | vector of probabilities.                    |
| n | number of random values to return.          |

|                         |                                                                                       |
|-------------------------|---------------------------------------------------------------------------------------|
| <code>lambda</code>     | vector of (non-negative) means.                                                       |
| <code>log, log.p</code> | logical; if TRUE, probabilities <code>p</code> are given as $\log(p)$ .               |
| <code>lower.tail</code> | logical; if TRUE (default), probabilities are $P[X \leq x]$ , otherwise, $P[X > x]$ . |

## Details

The Poisson distribution has density

$$p(x) = \frac{\lambda^x e^{-\lambda}}{x!}$$

for  $x = 0, 1, 2, \dots$ . The mean and variance are  $E(X) = Var(X) = \lambda$ .

Note that  $\lambda = 0$  is really a limit case (setting  $0^0 = 1$ ) resulting in a point mass at 0, see also the example.

If an element of `x` is not integer, the result of `dpois` is zero, with a warning.  $p(x)$  is computed using Loader's algorithm, see the reference in [dbinom](#).

The quantile is right continuous: `qpois(p, lambda)` is the smallest integer  $x$  such that  $P(X \leq x) \geq p$ .

Setting `lower.tail = FALSE` allows to get much more precise results when the default, `lower.tail = TRUE` would return 1, see the example below.

## Value

`dpois` gives the (log) density, `ppois` gives the (log) distribution function, `qpois` gives the quantile function, and `rpois` generates random deviates.

Invalid `lambda` will result in return value NaN, with a warning.

The length of the result is determined by `n` for `rpois`, and is the maximum of the lengths of the numerical arguments for the other functions.

The numerical arguments other than `n` are recycled to the length of the result. Only the first elements of the logical arguments are used.

`rpois` returns a vector of type [integer](#) unless generated values exceed the maximum representable integer when [double](#) values are returned.

## Source

`dpois` uses C code contributed by Catherine Loader (see [dbinom](#)).

`ppois` uses `pgamma`.

`qpois` uses the Cornish–Fisher Expansion to include a skewness correction to a normal approximation, followed by a search.

`rpois` uses

Ahrens, J. H. and Dieter, U. (1982). Computer generation of Poisson deviates from modified normal distributions. *ACM Transactions on Mathematical Software*, **8**, 163–179.

## See Also

[Distributions](#) for other standard distributions, including [dbinom](#) for the binomial and [dnbinom](#) for the negative binomial distribution.

[poisson.test](#).

## Examples

```
require(graphics)

-log(dpois(0:7, lambda = 1) * gamma(1+ 0:7)) # == 1
Ni <- rpois(50, lambda = 4); table(factor(Ni, 0:max(Ni)))

1 - ppois(10*(15:25), lambda = 100) # becomes 0 (cancellation)
  ppois(10*(15:25), lambda = 100, lower.tail = FALSE) # no cancellation

par(mfrow = c(2, 1))
x <- seq(-0.01, 5, 0.01)
plot(x, ppois(x, 1), type = "s", ylab = "F(x)", main = "Poisson(1) CDF")
plot(x, pbinom(x, 100, 0.01), type = "s", ylab = "F(x)",
      main = "Binomial(100, 0.01) CDF")

## The (limit) case lambda = 0 :
stopifnot(identical(dpois(0,0), 1),
          identical(ppois(0,0), 1),
          identical(qpois(1,0), 0))
```

---

poisson.test

*Exact Poisson tests*

---

## Description

Performs an exact test of a simple null hypothesis about the rate parameter in Poisson distribution, or for the ratio between two rate parameters.

## Usage

```
poisson.test(x, T = 1, r = 1,
             alternative = c("two.sided", "less", "greater"),
             conf.level = 0.95)
```

## Arguments

|                          |                                                                                                                                    |
|--------------------------|------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>           | number of events. A vector of length one or two.                                                                                   |
| <code>T</code>           | time base for event count. A vector of length one or two.                                                                          |
| <code>r</code>           | hypothesized rate or rate ratio                                                                                                    |
| <code>alternative</code> | indicates the alternative hypothesis and must be one of "two.sided", "greater" or "less". You can specify just the initial letter. |
| <code>conf.level</code>  | confidence level for the returned confidence interval.                                                                             |

## Details

Confidence intervals are computed similarly to those of [binom.test](#) in the one-sample case, and using [binom.test](#) in the two sample case.

**Value**

A list with class "htest" containing the following components:

|             |                                                                                            |
|-------------|--------------------------------------------------------------------------------------------|
| statistic   | the number of events (in the first sample if there are two.)                               |
| parameter   | the corresponding expected count                                                           |
| p.value     | the p-value of the test.                                                                   |
| conf.int    | a confidence interval for the rate or rate ratio.                                          |
| estimate    | the estimated rate or rate ratio.                                                          |
| null.value  | the rate or rate ratio under the null, $r$ .                                               |
| alternative | a character string describing the alternative hypothesis.                                  |
| method      | the character string "Exact Poisson test" or "Comparison of Poisson rates" as appropriate. |
| data.name   | a character string giving the names of the data.                                           |

**Note**

The rate parameter in Poisson data is often given based on a "time on test" or similar quantity (person-years, population size, or expected number of cases from mortality tables). This is the role of the  $T$  argument.

The one-sample case is effectively the binomial test with a very large  $n$ . The two sample case is converted to a binomial test by conditioning on the total event count, and the rate ratio is directly related to the odds in that binomial distribution.

**See Also**

[binom.test](#)

**Examples**

```
### These are paraphrased from data sets in the ISwR package

## SMR, Welsh Nickel workers
poisson.test(137, 24.19893)

## eba1977, compare Fredericia to other three cities for ages 55-59
poisson.test(c(11, 6+8+7), c(800, 1083+1050+878))
```

---

poly

---

*Compute Orthogonal Polynomials*

---

**Description**

Returns or evaluates orthogonal polynomials of degree 1 to degree over the specified set of points  $x$ : these are all orthogonal to the constant polynomial of degree 0. Alternatively, evaluate raw polynomials.

**Usage**

```
poly(x, ..., degree = 1, coefs = NULL, raw = FALSE, simple = FALSE)
polym(..., degree = 1, coefs = NULL, raw = FALSE)

## S3 method for class 'poly'
predict(object, newdata, ...)
```

**Arguments**

|            |                                                                                                                                                                                                       |
|------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| x, newdata | a numeric vector or an object with <a href="#">mode</a> "numeric" (such as a <a href="#">Date</a> ) at which to evaluate the polynomial. x can also be a matrix. Missing values are not allowed in x. |
| degree     | the degree of the polynomial. Must be less than the number of unique points when raw is false, as by default.                                                                                         |
| coefs      | for prediction, coefficients from a previous fit.                                                                                                                                                     |
| raw        | if true, use raw and not orthogonal polynomials.                                                                                                                                                      |
| simple     | logical indicating if a simple matrix (with no further <a href="#">attributes</a> but <a href="#">dimnames</a> ) should be returned. For speedup only.                                                |
| object     | an object inheriting from class "poly", normally the result of a call to poly with a single vector argument.                                                                                          |
| ...        | poly, polym: further vectors.<br>predict.poly: arguments to be passed to or from other methods.                                                                                                       |

**Details**

Although formally degree should be named (as it follows ...), an unnamed second argument of length 1 will be interpreted as the degree, such that `poly(x, 3)` can be used in formulas.

The orthogonal polynomial is summarized by the coefficients, which can be used to evaluate it via the three-term recursion given in Kennedy & Gentle (1980, pp. 343–4), and used in the predict part of the code.

poly using ... is just a convenience wrapper for polym: coef is ignored. Conversely, if polym is called with a single argument in ... it is a wrapper for poly.

**Value**

For poly and polym() (when simple=FALSE and coefs=NULL as per default):

A matrix with rows corresponding to points in x and columns corresponding to the degree, with attributes "degree" specifying the degrees of the columns and (unless raw = TRUE) "coefs" which contains the centering and normalization constants used in constructing the orthogonal polynomials and class `c("poly", "matrix")`.

For poly(\*, simple=TRUE), polym(\*, coefs=<non-NULL>), and predict.poly(): a matrix.

**Note**

This routine is intended for statistical purposes such as `contr.poly`: it does not attempt to orthogonalize to machine accuracy.

**Author(s)**

R Core Team. Keith Jewell (Campden BRI Group, UK) contributed improvements for correct prediction on subsets.

## Examples

```
od <- options(digits = 3) # avoid too much visual clutter
(z <- poly(1:10, 3))
predict(z, seq(2, 4, 0.5))
zapsmall(poly(seq(4, 6, 0.5), 3, coefs = attr(z, "coefs"))))

zm <- zapsmall(polym ( 1:4, c(1, 4:6), degree = 3)) # or just poly():
(z1 <- zapsmall(poly(cbind(1:4, c(1, 4:6)), degree = 3)))
## they are the same :
stopifnot(all.equal(zm, z1, tolerance = 1e-15))

## poly(<matrix>, df) --- used to fail till July 14 (vive la France!), 2017:
m2 <- cbind(1:4, c(1, 4:6))
pm2 <- zapsmall(poly(m2, 3)) # "unnamed degree = 3"
stopifnot(all.equal(pm2, zm, tolerance = 1e-15))

options(od)
```

---

power

*Create a Power Link Object*

---

## Description

Creates a link object based on the link function  $\eta = \mu^\lambda$ .

## Usage

```
power(lambda = 1)
```

## Arguments

lambda                      a real number.

## Details

If lambda is non-positive, it is taken as zero, and the log link is obtained. The default lambda = 1 gives the identity link.

## Value

A list with components linkfun, linkinv, mu.eta, and valideta. See [make.link](#) for information on their meaning.

## References

Chambers, J. M. and Hastie, T. J. (1992) *Statistical Models in S*. Wadsworth & Brooks/Cole.

## See Also

To raise a number to a power, see [Arithmetic](#).

To calculate the power of a test, see various functions in the **stats** package, e.g., [power.t.test](#).

## Examples

```
power()
quasi(link = power(1/3))[c("linkfun", "linkinv")]
```

---

power.anova.test

*Power Calculations for Balanced One-Way Analysis of Variance Tests*

---

## Description

Compute power of test or determine parameters to obtain target power.

## Usage

```
power.anova.test(groups = NULL, n = NULL,
                 between.var = NULL, within.var = NULL,
                 sig.level = 0.05, power = NULL)
```

## Arguments

|             |                                                   |
|-------------|---------------------------------------------------|
| groups      | Number of groups                                  |
| n           | Number of observations (per group)                |
| between.var | Between group variance                            |
| within.var  | Within group variance                             |
| sig.level   | Significance level (Type I error probability)     |
| power       | Power of test (1 minus Type II error probability) |

## Details

Exactly one of the parameters groups, n, between.var, power, within.var, and sig.level must be passed as NULL, and that parameter is determined from the others. Notice that sig.level has non-NULL default so NULL must be explicitly passed if you want it computed.

## Value

Object of class "power.htest", a list of the arguments (including the computed one) augmented with method and note elements.

## Note

uniroot is used to solve power equation for unknowns, so you may see errors from it, notably about inability to bracket the root when invalid arguments are given.

**Author(s)**

Claus Ekstrøm

**See Also**[anova](#), [lm](#), [uniroot](#)**Examples**

```
power.anova.test(groups = 4, n = 5, between.var = 1, within.var = 3)
# Power = 0.3535594

power.anova.test(groups = 4, between.var = 1, within.var = 3,
                  power = .80)
# n = 11.92613

## Assume we have prior knowledge of the group means:
groupmeans <- c(120, 130, 140, 150)
power.anova.test(groups = length(groupmeans),
                  between.var = var(groupmeans),
                  within.var = 500, power = .90) # n = 15.18834
```

power.prop.test

*Power Calculations for Two-Sample Test for Proportions***Description**

Compute the power of the two-sample test for proportions, or determine parameters to obtain a target power.

**Usage**

```
power.prop.test(n = NULL, p1 = NULL, p2 = NULL, sig.level = 0.05,
                power = NULL,
                alternative = c("two.sided", "one.sided"),
                strict = FALSE, tol = .Machine$double.eps^0.25)
```

**Arguments**

|             |                                                                                                     |
|-------------|-----------------------------------------------------------------------------------------------------|
| n           | number of observations (per group)                                                                  |
| p1          | probability in one group                                                                            |
| p2          | probability in other group                                                                          |
| sig.level   | significance level (Type I error probability)                                                       |
| power       | power of test (1 minus Type II error probability)                                                   |
| alternative | one- or two-sided test. Can be abbreviated.                                                         |
| strict      | use strict interpretation in two-sided case                                                         |
| tol         | numerical tolerance used in root finding, the default providing (at least) four significant digits. |

## Details

Exactly one of the parameters `n`, `p1`, `p2`, `power`, and `sig.level` must be passed as `NULL`, and that parameter is determined from the others. Notice that `sig.level` has a non-`NULL` default so `NULL` must be explicitly passed if you want it computed.

If `strict = TRUE` is used, the power will include the probability of rejection in the opposite direction of the true effect, in the two-sided case. Without this the power will be half the significance level if the true difference is zero.

Note that not all conditions can be satisfied, e.g., for

```
power.prop.test(n=30, p1=0.90, p2=NULL, power=0.8, strict=TRUE)
```

there is no proportion `p2` between `p1 = 0.9` and 1, as you'd need a sample size of at least  $n = 74$  to yield the desired power for  $(p1, p2) = (0.9, 1)$ .

For these impossible conditions, currently a warning ([warning](#)) is signalled which may become an error ([stop](#)) in the future.

## Value

Object of class `"power.htest"`, a list of the arguments (including the computed one) augmented with method and note elements.

## Note

[uniroot](#) is used to solve power equation for unknowns, so you may see errors from it, notably about inability to bracket the root when invalid arguments are given. If one of `p1` and `p2` is computed, then  $p1 < p2$  is assumed and will hold, but if you specify both,  $p2 \leq p1$  is allowed.

## Examples

```
power.prop.test(n = 50, p1 = .50, p2 = .75)      ## => power = 0.740
power.prop.test(p1 = .50, p2 = .75, power = .90) ## =>    n = 76.7
power.prop.test(n = 50, p1 = .5, power = .90)    ## =>    p2 = 0.8026
power.prop.test(n = 50, p1 = .5, p2 = 0.9, power = .90, sig.level=NULL)
                                                ## => sig.l = 0.00131
power.prop.test(p1 = .5, p2 = 0.501, sig.level=.001, power=0.90)
                                                ## => n = 10451937

try(
  power.prop.test(n=30, p1=0.90, p2=NULL, power=0.8)
) # a warning (which may become an error)
## Reason:
power.prop.test(      p1=0.90, p2= 1.0, power=0.8) ##-> n = 73.37
```

---

`power.t.test`*Power calculations for one and two sample t tests*

---

### Description

Compute the power of the one- or two- sample t test, or determine parameters to obtain a target power.

### Usage

```
power.t.test(n = NULL, delta = NULL, sd = 1, sig.level = 0.05,
             power = NULL,
             type = c("two.sample", "one.sample", "paired"),
             alternative = c("two.sided", "one.sided"),
             strict = FALSE, tol = .Machine$double.eps^0.25)
```

### Arguments

|                          |                                                                                                     |
|--------------------------|-----------------------------------------------------------------------------------------------------|
| <code>n</code>           | number of observations (per group)                                                                  |
| <code>delta</code>       | true difference in means                                                                            |
| <code>sd</code>          | standard deviation                                                                                  |
| <code>sig.level</code>   | significance level (Type I error probability)                                                       |
| <code>power</code>       | power of test (1 minus Type II error probability)                                                   |
| <code>type</code>        | string specifying the type of t test. Can be abbreviated.                                           |
| <code>alternative</code> | one- or two-sided test. Can be abbreviated.                                                         |
| <code>strict</code>      | use strict interpretation in two-sided case                                                         |
| <code>tol</code>         | numerical tolerance used in root finding, the default providing (at least) four significant digits. |

### Details

Exactly one of the parameters `n`, `delta`, `power`, `sd`, and `sig.level` must be passed as `NULL`, and that parameter is determined from the others. Notice that the last two have non-`NULL` defaults, so `NULL` must be explicitly passed if you want to compute them.

If `strict = TRUE` is used, the power will include the probability of rejection in the opposite direction of the true effect, in the two-sided case. Without this the power will be half the significance level if the true difference is zero.

### Value

Object of class `"power.htest"`, a list of the arguments (including the computed one) augmented with method and note elements.

### Note

`uniroot` is used to solve the power equation for unknowns, so you may see errors from it, notably about inability to bracket the root when invalid arguments are given.

|---------|--------------------------------------------|
| PP.test | <i>Phillips-Perron Test for Unit Roots</i> |
|---------|--------------------------------------------|

---

Description

Computes the Phillips-Perron test for the null hypothesis that  $x$  has a unit root against a stationary alternative.

Usage

```
PP.test(x, lshort = TRUE)
```

Arguments

|                     |                                                                                                 |
|---------------------|-------------------------------------------------------------------------------------------------|
| <code>x</code>      | a numeric vector or univariate time series.                                                     |
| <code>lshort</code> | a logical indicating whether the short or long version of the truncation lag parameter is used. |

Details

The general regression equation which incorporates a constant and a linear trend is used and the corrected t-statistic for a first order autoregressive coefficient equals one is computed. To estimate  $\sigma^2$  the Newey-West estimator is used. If `lshort` is `TRUE`, then the truncation lag parameter is set to `trunc(4*(n/100)^0.25)`, otherwise `trunc(12*(n/100)^0.25)` is used. The p-values are interpolated from Table 4.2, page 103 of Banerjee et al. (1993).  
Missing values are not handled.

Value

A list with class `"htest"` containing the following components:

|                        |                                                                |
|------------------------|----------------------------------------------------------------|
| <code>statistic</code> | the value of the test statistic.                               |
| <code>parameter</code> | the truncation lag parameter.                                  |
| <code>p.value</code>   | the p-value of the test.                                       |
| <code>method</code>    | a character string indicating what type of test was performed. |
| <code>data.name</code> | a character string giving the name of the data.                |

```
x <- rnorm(1000)
PP.test(x)
y <- cumsum(x) # has unit root
PP.test(y)
```

ppoints

*Ordinates for Probability Plotting***Description**

Generates the sequence of probability points  $(1:m-a)/(m+(1-a)-a)$  where  $m$  is either  $n$ , if  $\text{length}(n)=1$ , or  $\text{length}(n)$ .

**Usage**

```
ppoints(n, a = if(n <= 10) 3/8 else 1/2)
```

**Arguments**

$n$  either the number of points generated or a vector of observations.

$a$  the offset fraction to be used; typically in  $(0, 1)$ .

**Details**

If  $0 < a < 1$ , the resulting values are within  $(0, 1)$  (excluding boundaries). In any case, the resulting sequence is symmetric in  $[0, 1]$ , i.e.,  $p + \text{rev}(p) == 1$ .

`ppoints()` is used in `qqplot` and `qqnorm` to generate the set of probabilities at which to evaluate the inverse distribution.

The choice of  $a$  follows the documentation of the function of the same name in Becker et al. (1988), and appears to have been motivated by results from Blom (1958) on approximations to expected normal order statistics (see also [quantile](#)).

The probability points for the continuous sample quantile types 5 to 9 (see [quantile](#)) can be obtained by taking  $a$  as, respectively,  $1/2$ ,  $0$ ,  $1$ ,  $1/3$ , and  $3/8$ .

 ppr

*Projection Pursuit Regression*

---

**Description**

Fit a projection pursuit regression model.

**Usage**

```
ppr(x, ...)
```

## S3 method for class 'formula'

```
ppr(formula, data, weights, subset, na.action,
    contrasts = NULL, ..., model = FALSE)
```

## Default S3 method:

```
ppr(x, y, weights = rep(1, n),
    ww = rep(1, q), nterms, max.terms = nterms, optlevel = 2,
    sm.method = c("supsmu", "spline", "gcv spline"),
    bass = 0, span = 0, df = 5, gcvpen = 1, trace = FALSE, ...)
```

**Arguments**

|           |                                                                                                                                                                                                                                                                                                                                                                                       |
|-----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| formula   | a formula specifying one or more numeric response variables and the explanatory variables.                                                                                                                                                                                                                                                                                            |
| x         | numeric matrix of explanatory variables. Rows represent observations, and columns represent variables. Missing values are not accepted.                                                                                                                                                                                                                                               |
| y         | numeric matrix of response variables. Rows represent observations, and columns represent variables. Missing values are not accepted.                                                                                                                                                                                                                                                  |
| nterms    | number of terms to include in the final model.                                                                                                                                                                                                                                                                                                                                        |
| data      | a data frame (or similar: see <a href="#">model.frame</a> ) from which variables specified in formula are preferentially to be taken.                                                                                                                                                                                                                                                 |
| weights   | a vector of weights $w_i$ for each <i>case</i> .                                                                                                                                                                                                                                                                                                                                      |
| ww        | a vector of weights for each <i>response</i> , so the fit criterion is the sum over case $i$ and responses $j$ of $w_i ww_j (y_{ij} - \text{fit}_{ij})^2$ divided by the sum of $w_i$ .                                                                                                                                                                                               |
| subset    | an index vector specifying the cases to be used in the training sample. (NOTE: If given, this argument must be named.)                                                                                                                                                                                                                                                                |
| na.action | a function to specify the action to be taken if <b>NA</b> s are found. The default action is given by <code>getOption("na.action")</code> . (NOTE: If given, this argument must be named.)                                                                                                                                                                                            |
| contrasts | the contrasts to be used when any factor explanatory variables are coded.                                                                                                                                                                                                                                                                                                             |
| max.terms | maximum number of terms to choose from when building the model.                                                                                                                                                                                                                                                                                                                       |
| optlevel  | integer from 0 to 3 which determines the thoroughness of an optimization routine in the SMART program. See the ‘Details’ section.                                                                                                                                                                                                                                                     |
| sm.method | the method used for smoothing the ridge functions. The default is to use Friedman’s super smoother <a href="#">supsmu</a> . The alternatives are to use the smoothing spline code underlying <a href="#">smooth.spline</a> , either with a specified (equivalent) degrees of freedom for each ridge functions, or to allow the smoothness to be chosen by GCV.<br>Can be abbreviated. |
| bass      | super smoother bass tone control used with automatic span selection (see <a href="#">supsmu</a> ); the range of values is 0 to 10, with larger values resulting in increased smoothing.                                                                                                                                                                                               |
| span      | super smoother span control (see <a href="#">supsmu</a> ). The default, 0, results in automatic span selection by local cross validation. span can also take a value in $(0, 1]$ .                                                                                                                                                                                                    |
| df        | if <code>sm.method</code> is "spline" specifies the smoothness of each ridge term via the requested equivalent degrees of freedom.                                                                                                                                                                                                                                                    |
| gcvpen    | if <code>sm.method</code> is "gcv spline" this is the penalty used in the GCV selection for each degree of freedom used.                                                                                                                                                                                                                                                              |
| trace     | logical indicating if each spline fit should produce diagnostic output (about $\lambda$ and $df$ ), and the <a href="#">supsmu</a> fit about its steps.                                                                                                                                                                                                                               |
| ...       | arguments to be passed to or from other methods.                                                                                                                                                                                                                                                                                                                                      |
| model     | logical. If true, the model frame is returned.                                                                                                                                                                                                                                                                                                                                        |

## Details

The basic method is given by Friedman (1984) and based on his code. This code has been shown to be extremely sensitive to the Fortran compiler used.

The algorithm first adds up to `max.terms` ridge terms one at a time; it will use less if it is unable to find a term to add that makes sufficient difference. It then removes the least important term at each step until `nterms` terms are left.

The levels of optimization (argument `optlevel`) differ in how thoroughly the models are refitted during this process. At level 0 the existing ridge terms are not refitted. At level 1 the projection directions are not refitted, but the ridge functions and the regression coefficients are. Levels 2 and 3 refit all the terms and are equivalent for one response; level 3 is more careful to re-balance the contributions from each regressor at each step and so is a little less likely to converge to a saddle point of the sum of squares criterion.

## Value

A list with the following components, many of which are for use by the method functions.

|                            |                                                                                                                                                                           |
|----------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>call</code>          | the matched call                                                                                                                                                          |
| <code>p</code>             | the number of explanatory variables (after any coding)                                                                                                                    |
| <code>q</code>             | the number of response variables                                                                                                                                          |
| <code>mu</code>            | the argument <code>nterms</code>                                                                                                                                          |
| <code>ml</code>            | the argument <code>max.terms</code>                                                                                                                                       |
| <code>gof</code>           | the overall residual (weighted) sum of squares for the selected model                                                                                                     |
| <code>gofn</code>          | the overall residual (weighted) sum of squares against the number of terms, up to <code>max.terms</code> . Will be invalid (and zero) for less than <code>nterms</code> . |
| <code>df</code>            | the argument <code>df</code>                                                                                                                                              |
| <code>edf</code>           | if <code>sm.method</code> is "spline" or "gcv spline" the equivalent number of degrees of freedom for each ridge term used.                                               |
| <code>xnames</code>        | the names of the explanatory variables                                                                                                                                    |
| <code>yname</code> s       | the names of the response variables                                                                                                                                       |
| <code>alpha</code>         | a matrix of the projection directions, with a column for each ridge term                                                                                                  |
| <code>beta</code>          | a matrix of the coefficients applied for each response to the ridge terms: the rows are the responses and the columns the ridge terms                                     |
| <code>yb</code>            | the weighted means of each response                                                                                                                                       |
| <code>ys</code>            | the overall scale factor used: internally the responses are divided by <code>ys</code> to have unit total weighted sum of squares.                                        |
| <code>fitted.values</code> | the fitted values, as a matrix if <code>q &gt; 1</code> .                                                                                                                 |
| <code>residuals</code>     | the residuals, as a matrix if <code>q &gt; 1</code> .                                                                                                                     |
| <code>smod</code>          | internal work array, which includes the ridge functions evaluated at the training set points.                                                                             |
| <code>model</code>         | (only if <code>model = TRUE</code> ) the model frame.                                                                                                                     |

prcomp

*Principal Components Analysis***Description**

Performs a principal components analysis on the given data matrix and returns the results as an object of class `prcomp`.

**Usage**

```
prcomp(x, ...)

## S3 method for class 'formula'
prcomp(formula, data = NULL, subset, na.action, ...)

## Default S3 method:
prcomp(x, retx = TRUE, center = TRUE, scale. = FALSE,
       tol = NULL, rank. = NULL, ...)

## S3 method for class 'prcomp'
predict(object, newdata, ...)
```

**Arguments**

|                        |                                                                                                                                                                                                                                                                                                                                                                        |
|------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>formula</code>   | a formula with no response variable, referring only to numeric variables.                                                                                                                                                                                                                                                                                              |
| <code>data</code>      | an optional data frame (or similar: see <a href="#">model.frame</a> ) containing the variables in the formula <code>formula</code> . By default the variables are taken from <code>environment(formula)</code> .                                                                                                                                                       |
| <code>subset</code>    | an optional vector used to select rows (observations) of the data matrix <code>x</code> .                                                                                                                                                                                                                                                                              |
| <code>na.action</code> | a function which indicates what should happen when the data contain NAs. The default is set by the <code>na.action</code> setting of <a href="#">options</a> , and is <a href="#">na.fail</a> if that is unset. The ‘factory-fresh’ default is <a href="#">na.omit</a> .                                                                                               |
| <code>...</code>       | arguments passed to or from other methods. If <code>x</code> is a formula one might specify <code>scale.</code> or <code>tol</code> .                                                                                                                                                                                                                                  |
| <code>x</code>         | a numeric or complex matrix (or data frame) which provides the data for the principal components analysis.                                                                                                                                                                                                                                                             |
| <code>retx</code>      | a logical value indicating whether the rotated variables should be returned.                                                                                                                                                                                                                                                                                           |
| <code>center</code>    | a logical value indicating whether the variables should be shifted to be zero centered. Alternately, a vector of length equal the number of columns of <code>x</code> can be supplied. The value is passed to <code>scale.</code>                                                                                                                                      |
| <code>scale.</code>    | a logical value indicating whether the variables should be scaled to have unit variance before the analysis takes place. The default is <code>FALSE</code> for consistency with S, but in general scaling is advisable. Alternatively, a vector of length equal the number of columns of <code>x</code> can be supplied. The value is passed to <a href="#">scale.</a> |
| <code>tol</code>       | a value indicating the magnitude below which components should be omitted. (Components are omitted if their standard deviations are less than or equal to <code>tol</code> times the standard deviation of the first component.) With the default null setting, no components are omitted (unless <code>rank.</code> is specified                                      |

|                      |                                                                                                                                                                                                                                                                                                                                                              |
|----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                      | less than $\min(\dim(x))$ ). Other settings for <code>tol</code> could be <code>tol = 0</code> or <code>tol = sqrt(.Machine\$double.eps)</code> , which would omit essentially constant components.                                                                                                                                                          |
| <code>rank</code>    | optionally, a number specifying the maximal rank, i.e., maximal number of principal components to be used. Can be set as alternative or in addition to <code>tol</code> , useful notably when the desired rank is considerably smaller than the dimensions of the matrix.                                                                                    |
| <code>object</code>  | object of class inheriting from "prcomp"                                                                                                                                                                                                                                                                                                                     |
| <code>newdata</code> | An optional data frame or matrix in which to look for variables with which to predict. If omitted, the scores are used. If the original fit used a formula or a data frame or a matrix with column names, <code>newdata</code> must contain columns with the same names. Otherwise it must contain the same number of columns, to be used in the same order. |

### Details

The calculation is done by a singular value decomposition of the (centered and possibly scaled) data matrix, not by using `eigen` on the covariance matrix. This is generally the preferred method for numerical accuracy. The `print` method for these objects prints the results in a nice format and the `plot` method produces a scree plot.

Unlike `princomp`, variances are computed with the usual divisor  $N - 1$ .

Note that `scale = TRUE` cannot be used if there are zero or constant (for `center = TRUE`) variables.

### Value

`prcomp` returns a list with class "prcomp" containing the following components:

|                            |                                                                                                                                                                                                                                                                                                                                                                            |
|----------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>sdev</code>          | the standard deviations of the principal components (i.e., the square roots of the eigenvalues of the covariance/correlation matrix, though the calculation is actually done with the singular values of the data matrix).                                                                                                                                                 |
| <code>rotation</code>      | the matrix of variable loadings (i.e., a matrix whose columns contain the eigenvectors). The function <code>princomp</code> returns this in the element <code>loadings</code> .                                                                                                                                                                                            |
| <code>x</code>             | if <code>retx</code> is true the value of the rotated data (the centred (and scaled if requested) data multiplied by the rotation matrix) is returned. Hence, <code>cov(x)</code> is the diagonal matrix <code>diag(sdev^2)</code> . For the formula method, <code>napredict()</code> is applied to handle the treatment of values omitted by the <code>na.action</code> . |
| <code>center, scale</code> | the centering and scaling used, or <code>FALSE</code> .                                                                                                                                                                                                                                                                                                                    |

### Note

The signs of the columns of the rotation matrix are arbitrary, and so may differ between different programs for PCA, and even between different builds of R.

biplot(prcomp(USArrests, scale. = TRUE))
```

---

predict

*Model Predictions*

---

**Description**

`predict` is a generic function for predictions from the results of various model fitting functions. The function invokes particular *methods* which depend on the [class](#) of the first argument.

**Usage**

```
predict(object, ...)
```

**Arguments**

|                     |                                                          |
|---------------------|----------------------------------------------------------|
| <code>object</code> | a model object for which prediction is desired.          |
| <code>...</code>    | additional arguments affecting the predictions produced. |

## Details

Most prediction methods which are similar to those for linear models have an argument `newdata` specifying the first place to look for explanatory variables to be used for prediction. Some considerable attempts are made to match up the columns in `newdata` to those used for fitting, for example that they are of comparable types and that any factors have the same level set in the same order (or can be transformed to be so).

Time series prediction methods in package **stats** have an argument `n.ahead` specifying how many time steps ahead to predict.

Many methods have a logical argument `se.fit` saying if standard errors are to be returned.

## Value

The form of the value returned by `predict` depends on the class of its argument. See the documentation of the particular methods for details of what is produced by that method.

## References

Chambers, J. M. and Hastie, T. J. (1992) *Statistical Models in S*. Wadsworth & Brooks/Cole.

## See Also

[predict.glm](#), [predict.lm](#), [predict.loess](#), [predict.nls](#), [predict.poly](#), [predict.princomp](#), [predict.smooth.spline](#).

[SafePrediction](#) for prediction from (univariable) polynomial and spline fits.

For time-series prediction, [predict.ar](#), [predict.Arima](#), [predict.arima0](#), [predict.HoltWinters](#), [predict.StructTS](#).

## Examples

```
require(utils)

## All the "predict" methods found
## NB most of the methods in the standard packages are hidden.
## Output will depend on what namespaces are (or have been) loaded.

for(fn in methods("predict"))
  try({
    f <- eval(substitute(getAnywhere(fn)$objs[[1]]), list(fn = fn))
    cat(fn, ":\n\t", deparse(args(f)), "\n")
  }, silent = TRUE)
```

---

`predict.Arima`

*Forecast from ARIMA fits*

---

## Description

Forecast from models fitted by [arima](#).

**Usage**

```
## S3 method for class 'Arima'
predict(object, n.ahead = 1, newxreg = NULL,
        se.fit = TRUE, ...)
```

**Arguments**

|         |                                                                                |
|---------|--------------------------------------------------------------------------------|
| object  | The result of an arima fit.                                                    |
| n.ahead | The number of steps ahead for which prediction is required.                    |
| newxreg | New values of xreg to be used for prediction. Must have at least n.ahead rows. |
| se.fit  | Logical: should standard errors of prediction be returned?                     |
| ...     | arguments passed to or from other methods.                                     |

**Details**

Finite-history prediction is used, via [KalmanForecast](#). This is only statistically efficient if the MA part of the fit is invertible, so `predict.Arima` will give a warning for non-invertible MA models.

The standard errors of prediction exclude the uncertainty in the estimation of the ARMA model and the regression coefficients. According to Harvey (1993, pp. 58–9) the effect is small.

**Value**

A time series of predictions, or if `se.fit = TRUE`, a list with components `pred`, the predictions, and `se`, the estimated standard errors. Both components are time series.

**Examples**

```
od <- options(digits = 5) # avoid too much spurious accuracy
predict(arima(lh, order = c(3,0,0)), n.ahead = 12)

(fit <- arima(USAccDeaths, order = c(0,1,1),
             seasonal = list(order = c(0,1,1))))
predict(fit, n.ahead = 6)
options(od)
```

predict.glm

*Predict Method for GLM Fits***Description**

Obtains predictions and optionally estimates standard errors of those predictions from a fitted generalized linear model object.

**Usage**

```
## S3 method for class 'glm'
predict(object, newdata = NULL,
        type = c("link", "response", "terms"),
        se.fit = FALSE, dispersion = NULL, terms = NULL,
        na.action = na.pass, ...)
```

**Arguments**

|                         |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|-------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>object</code>     | a fitted object of class inheriting from "glm".                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <code>newdata</code>    | optionally, a data frame in which to look for variables with which to predict. If omitted, the fitted linear predictors are used.                                                                                                                                                                                                                                                                                                                                                                                          |
| <code>type</code>       | the type of prediction required. The default is on the scale of the linear predictors; the alternative "response" is on the scale of the response variable. Thus for a default binomial model the default predictions are of log-odds (probabilities on logit scale) and <code>type = "response"</code> gives the predicted probabilities. The "terms" option returns a matrix giving the fitted values of each term in the model formula on the linear predictor scale.<br>The value of this argument can be abbreviated. |
| <code>se.fit</code>     | logical switch indicating if standard errors are required.                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <code>dispersion</code> | the dispersion of the GLM fit to be assumed in computing the standard errors. If omitted, that returned by <code>summary</code> applied to the object is used.                                                                                                                                                                                                                                                                                                                                                             |
| <code>terms</code>      | with <code>type = "terms"</code> by default all terms are returned. A character vector specifies which terms are to be returned                                                                                                                                                                                                                                                                                                                                                                                            |
| <code>na.action</code>  | function determining what should be done with missing values in <code>newdata</code> . The default is to predict NA.                                                                                                                                                                                                                                                                                                                                                                                                       |
| <code>...</code>        | further arguments passed to or from other methods.                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

**Details**

If `newdata` is omitted the predictions are based on the data used for the fit. In that case how cases with missing values in the original fit is determined by the `na.action` argument of that fit. If `na.action = na.omit` omitted cases will not appear in the residuals, whereas if `na.action = na.exclude` they will appear (in predictions and standard errors), with residual value NA. See also [napredict](#).

**Value**

If `se.fit = FALSE`, a vector or matrix of predictions. For `type = "terms"` this is a matrix with a column per term, and may have an attribute `"constant"`.

If `se.fit = TRUE`, a list with components

|                             |                                                                                          |
|-----------------------------|------------------------------------------------------------------------------------------|
| <code>fit</code>            | Predictions, as for <code>se.fit = FALSE</code> .                                        |
| <code>se.fit</code>         | Estimated standard errors.                                                               |
| <code>residual.scale</code> | A scalar giving the square root of the dispersion used in computing the standard errors. |

**Note**

Variables are first looked for in `newdata` and then searched for in the usual way (which will include the environment of the formula used in the fit). A warning will be given if the variables found are not of the same length as those in `newdata` if it was supplied.

**Examples**

```
require(graphics)

## example from Venables and Ripley (2002, pp. 190-2.)
ldose <- rep(0:5, 2)
numdead <- c(1, 4, 9, 13, 18, 20, 0, 2, 6, 10, 12, 16)
sex <- factor(rep(c("M", "F"), c(6, 6)))
SF <- cbind(numdead, numalive = 20-numdead)
budworm.lg <- glm(SF ~ sex*ldose, family = binomial)
summary(budworm.lg)

plot(c(1,32), c(0,1), type = "n", xlab = "dose",
      ylab = "prob", log = "x")
text(2^ldose, numdead/20, as.character(sex))
ld <- seq(0, 5, 0.1)
lines(2^ld, predict(budworm.lg, data.frame(ldose = ld,
      sex = factor(rep("M", length(ld)), levels = levels(sex))),
      type = "response"))
lines(2^ld, predict(budworm.lg, data.frame(ldose = ld,
      sex = factor(rep("F", length(ld)), levels = levels(sex))),
      type = "response"))
```

---

predict.HoltWinters      *Prediction Function for Fitted Holt-Winters Models*

---

**Description**

Computes predictions and prediction intervals for models fitted by the Holt-Winters method.

**Usage**

```
## S3 method for class 'HoltWinters'
predict(object, n.ahead = 1, prediction.interval = FALSE,
        level = 0.95, ...)
```

**Arguments**

|                     |                                                                                                      |
|---------------------|------------------------------------------------------------------------------------------------------|
| object              | An object of class HoltWinters.                                                                      |
| n.ahead             | Number of future periods to predict.                                                                 |
| prediction.interval | logical. If TRUE, the lower and upper bounds of the corresponding prediction intervals are computed. |
| level               | Confidence level for the prediction interval.                                                        |
| ...                 | arguments passed to or from other methods.                                                           |

**Value**

A time series of the predicted values. If prediction intervals are requested, a multiple time series is returned with columns `fit`, `lwr` and `upr` for the predicted values and the lower and upper bounds respectively.

predict.lm

*Predict method for Linear Model Fits***Description**

Predicted values based on linear model object.

**Usage**

```
## S3 method for class 'lm'
predict(object, newdata, se.fit = FALSE, scale = NULL, df = Inf,
        interval = c("none", "confidence", "prediction"),
        level = 0.95, type = c("response", "terms"),
        terms = NULL, na.action = na.pass,
        pred.var = res.var/weights, weights = 1,
        rankdeficient = c("warnif", "simple", "non-estim", "NA", "NAwarn"),
        tol = 1e-6, verbose = FALSE,
        ...)
```

**Arguments**

|               |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|---------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| object        | Object of class inheriting from "lm"                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| newdata       | An optional data frame in which to look for variables with which to predict. If omitted, the fitted values are used.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| se.fit        | A switch indicating if standard errors are required.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| scale         | Scale parameter for std.err. calculation.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| df            | Degrees of freedom for scale.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| interval      | Type of interval calculation. Can be abbreviated.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| level         | Tolerance/confidence level.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| type          | Type of prediction (response or model term). Can be abbreviated.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| terms         | If type = "terms", which terms (default is all terms), a <a href="#">character</a> vector.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| na.action     | function determining what should be done with missing values in newdata. The default is to predict NA.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| pred.var      | the variance(s) for future observations to be assumed for prediction intervals. See 'Details'.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| weights       | variance weights for prediction. This can be a numeric vector or a one-sided model formula. In the latter case, it is interpreted as an expression evaluated in newdata.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| rankdeficient | <p>a <a href="#">character</a> string specifying what should happen in the case of a rank deficient model, i.e., when <code>object\$rank &lt; ncol(model.matrix(object))</code>.</p> <p>"warnif": gives a <a href="#">warning</a> only in case of predicting 'non-estimable' cases, i.e., vectors not in the same predictor subspace as the original data (with tolerance tol). In that case, the non-estimable indices are also returned as attribute "non-estim" (see <code>rankdeficient="non-estim"</code>).</p> <p>"simple": is back compatible to R &lt; 4.3.0, possibly giving dubious predictions in non-estimable cases, and always signalling a <a href="#">warning</a>.</p> |

|                      |                                                                                                                                                                                                                                         |
|----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                      | "non-estim": gives the same predictions without <a href="#">warning</a> , and with an attribute <code>attr(*, "non-estim")</code> with indices in <code>1:nrow(newdata)</code> of new data observations which are deemed non-estimable. |
|                      | "NA": predicts NA for non-estimable new data, silently. Often recommended in new code.                                                                                                                                                  |
|                      | "NAwarn": predicts NA for non-estimable new data with a <a href="#">warning</a> .                                                                                                                                                       |
| <code>tol</code>     | non-negative number determining how non-estimability is determined in rank deficient cases.                                                                                                                                             |
| <code>verbose</code> | <a href="#">logical</a> indicating if messages should be produced about rank deficiency handling.                                                                                                                                       |
| <code>...</code>     | further arguments passed to or from other methods.                                                                                                                                                                                      |

## Details

`predict.lm` produces predicted values, obtained by evaluating the regression function in the frame `newdata` (which defaults to `model.frame(object)`). If the logical `se.fit` is TRUE, standard errors of the predictions are calculated. If the numeric argument `scale` is set (with optional `df`), it is used as the residual standard deviation in the computation of the standard errors, otherwise this is extracted from the model fit. Setting `intervals` specifies computation of confidence or prediction (tolerance) intervals at the specified `level`, sometimes referred to as narrow vs. wide intervals.

If the fit is rank-deficient, some of the columns of the design matrix will have been dropped during the `lm` computations, and corresponding `coef()` components set to NA. Prediction from such a fit only makes sense if `newdata` is contained in the same subspace as the original data. Other `newdata` entries (rows) are non-estimable. This is now checked (up to numerical tolerance `tol`) unless `rankdeficient == "simple"`, which corresponds to previous behaviour, warns always and predicts using the non-NA coefficients with the corresponding columns of the design matrix. The new default option, `rankdeficient == "warnif"` checks if there are "non-estimable" cases (up to tolerance `tol`) and only warns in that case. All further `rankdeficient` options also check and either predict NA or mark the non-estimable cases differently.

If `newdata` is omitted the predictions are based on the data used for the fit. In that case how cases with missing values in the original fit are handled is determined by the `na.action` argument of that fit. If `na.action = na.omit` omitted cases will not appear in the predictions, whereas if `na.action = na.exclude` they will appear (in predictions, standard errors or interval limits), with value NA. See also [napredict](#).

The prediction intervals are for a single observation at each case in `newdata` (or by default, the data used for the fit) with error variance(s) `pred.var`. This can be a multiple of `res.var`, the estimated value of  $\sigma^2$ : the default is to assume that future observations have the same error variance as those used for fitting. If `weights` is supplied, the inverse of this is used as a scale factor. For a weighted fit, if the prediction is for the original data frame, `weights` defaults to the weights used for the model fit, with a warning since it might not be the intended result. If the fit was weighted and `newdata` is given, the default is to assume constant prediction variance, with a warning.

## Value

`predict.lm` produces a vector of predictions or a matrix of predictions and bounds with column names `fit`, `lwr`, and `upr` if `interval` is set. For type = "terms" this is a matrix with a column per term and may have an attribute "constant".

If `se.fit` is TRUE, a list with the following components is returned:

|                     |                                   |
|---------------------|-----------------------------------|
| <code>fit</code>    | vector or matrix as above         |
| <code>se.fit</code> | standard error of predicted means |

residual.scale    residual standard deviations  
df                degrees of freedom for residual

### Note

Variables are first looked for in `newdata` and then searched for in the usual way (which will include the environment of the formula used in the fit). A warning will be given if the variables found are not of the same length as those in `newdata` if it was supplied.

Notice that prediction variances and prediction intervals always refer to *future* observations, possibly corresponding to the same predictors as used for the fit. The variance of the *residuals* will be smaller.

Strictly speaking, the formula used for prediction limits assumes that the degrees of freedom for the fit are the same as those for the residual variance. This may not be the case if `res.var` is not obtained from the fit.

|---------------|---------------------------------------|
| predict.loess | <i>Predict LOESS Curve or Surface</i> |
|---------------|---------------------------------------|

---

## Description

Predictions from a loess fit, optionally with standard errors.

## Usage

```
## S3 method for class 'loess'
predict(object, newdata = NULL, se = FALSE,
        na.action = na.pass, ...)
```

## Arguments

|           |                                                                                                                                                                                                          |
|-----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| object    | an object fitted by loess.                                                                                                                                                                               |
| newdata   | an optional data frame in which to look for variables with which to predict, or a matrix or vector containing exactly the variables needs for prediction. If missing, the original data points are used. |
| se        | should standard errors be computed?                                                                                                                                                                      |
| na.action | function determining what should be done with missing values in data frame newdata. The default is to predict NA.                                                                                        |
| ...       | arguments passed to or from other methods.                                                                                                                                                               |

## Details

The standard errors calculation `se = TRUE` is slower than prediction, notably as it needs a relatively large workspace (memory), notably matrices of dimension  $N \times Nf$  where  $f = \text{span}$ , i.e., `se = TRUE` is  $O(N^2)$  and hence stops when the sample size  $N$  is larger than about 40'600 (for default `span = 0.75`).

When the fit was made using `surface = "interpolate"` (the default), `predict.loess` will not extrapolate – so points outside an axis-aligned hypercube enclosing the original data will have missing (NA) predictions and standard errors.

## Value

If `se = FALSE`, a vector giving the prediction for each row of `newdata` (or the original data). If `se = TRUE`, a list containing components

|                |                                                                                                                                            |
|----------------|--------------------------------------------------------------------------------------------------------------------------------------------|
| fit            | the predicted values.                                                                                                                      |
| se             | an estimated standard error for each predicted value.                                                                                      |
| residual.scale | the estimated scale of the residuals used in computing the standard errors.                                                                |
| df             | an estimate of the effective degrees of freedom used in estimating the residual scale, intended for use with t-based confidence intervals. |

If `newdata` was the result of a call to [expand.grid](#), the predictions (and s.e.'s if requested) will be an array of the appropriate dimensions.

Predictions from infinite inputs will be NA since loess does not support extrapolation.

**Note**

Variables are first looked for in `newdata` and then searched for in the usual way (which will include the environment of the formula used in the fit). A warning will be given if the variables found are not of the same length as those in `newdata` if it was supplied.

**Examples**

```
cars.lo <- loess(dist ~ speed, cars)
predict(cars.lo, data.frame(speed = seq(5, 30, 1)), se = TRUE)
# to get extrapolation
cars.lo2 <- loess(dist ~ speed, cars,
  control = loess.control(surface = "direct"))
predict(cars.lo2, data.frame(speed = seq(5, 30, 1)), se = TRUE)
```

---

predict.nls

*Predicting from Nonlinear Least Squares Fits*

---

**Description**

`predict.nls` produces predicted values, obtained by evaluating the regression function in the frame `newdata`. If the logical `se.fit` is `TRUE`, standard errors of the predictions are calculated. If the numeric argument `scale` is set (with optional `df`), it is used as the residual standard deviation in the computation of the standard errors, otherwise this is extracted from the model fit. Setting `intervals` specifies computation of confidence or prediction (tolerance) intervals at the specified level.

At present `se.fit` and `interval` are ignored.

**Usage**

```
## S3 method for class 'nls'
predict(object, newdata, se.fit = FALSE, scale = NULL, df = Inf,
  interval = c("none", "confidence", "prediction"),
  level = 0.95, ...)
```

**Arguments**

|                      |                                                                                                                                                                                 |
|----------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>object</code>  | An object that inherits from class <code>nls</code> .                                                                                                                           |
| <code>newdata</code> | A named list or data frame in which to look for variables with which to predict. If <code>newdata</code> is missing the fitted values at the original data points are returned. |
| <code>se.fit</code>  | A logical value indicating if the standard errors of the predictions should be calculated. Defaults to <code>FALSE</code> . At present this argument is ignored.                |

|          |                                                                                                                                                                                                                                              |
|----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| scale    | A numeric scalar. If it is set (with optional df), it is used as the residual standard deviation in the computation of the standard errors, otherwise this information is extracted from the model fit. At present this argument is ignored. |
| df       | A positive numeric scalar giving the number of degrees of freedom for the scale estimate. At present this argument is ignored.                                                                                                               |
| interval | A character string indicating if prediction intervals or a confidence interval on the mean responses are to be calculated. At present this argument is ignored.                                                                              |
| level    | A numeric scalar between 0 and 1 giving the confidence level for the intervals (if any) to be calculated. At present this argument is ignored.                                                                                               |
| ...      | Additional optional arguments. At present no optional arguments are used.                                                                                                                                                                    |

### Value

`predict.nls` produces a vector of predictions. When implemented, `interval` will produce a matrix of predictions and bounds with column names `fit`, `lwr`, and `upr`. When implemented, if `se.fit` is TRUE, a list with the following components will be returned:

|                             |                                 |
|-----------------------------|---------------------------------|
| <code>fit</code>            | vector or matrix as above       |
| <code>se.fit</code>         | standard error of predictions   |
| <code>residual.scale</code> | residual standard deviations    |
| <code>df</code>             | degrees of freedom for residual |

### Note

Variables are first looked for in `newdata` and then searched for in the usual way (which will include the environment of the formula used in the fit). A warning will be given if the variables found are not of the same length as those in `newdata` if it was supplied.

lines(tt, predict(fm, list(Time = tt)))
par(opar)
```

---

predict.smooth.spline *Predict from Smoothing Spline Fit*

---

## Description

Predict a smoothing spline fit at new points, return the derivative if desired. The predicted fit is linear beyond the original data.

## Usage

```
## S3 method for class 'smooth.spline'
predict(object, x, deriv = 0, ...)
```

## Arguments

|        |                                                    |
|--------|----------------------------------------------------|
| object | a fit from smooth.spline.                          |
| x      | the new values of x.                               |
| deriv  | integer; the order of the derivative required.     |
| ...    | further arguments passed to or from other methods. |

## Value

A list with components

|   |                                        |
|---|----------------------------------------|
| x | The input x.                           |
| y | The fitted values or derivatives at x. |

preplot

*Pre-computations for a Plotting Object***Description**

Compute an object to be used for plots relating to the given model object.

**Usage**

```
preplot(object, ...)
```

**Arguments**

|        |                                            |
|--------|--------------------------------------------|
| object | a fitted model object.                     |
| ...    | additional arguments for specific methods. |

**Details**

Only the generic function is currently provided in base R, but some add-on packages have methods. Principally here for S compatibility.

**Value**

An object set up to make a plot that describes object.

princomp

*Principal Components Analysis***Description**

princomp performs a principal components analysis on the given numeric data matrix and returns the results as an object of class princomp.

**Usage**

```

princomp(x, ...)

## S3 method for class 'formula'
princomp(formula, data = NULL, subset, na.action, ...)

## Default S3 method:
princomp(x, cor = FALSE, scores = TRUE, covmat = NULL,
         subset = rep_len(TRUE, nrow(as.matrix(x))), fix_sign = TRUE, ...)

## S3 method for class 'princomp'
predict(object, newdata, ...)

```

**Arguments**

|           |                                                                                                                                                                                                                                                                                                                                                 |
|-----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| formula   | a formula with no response variable, referring only to numeric variables.                                                                                                                                                                                                                                                                       |
| data      | an optional data frame (or similar: see <a href="#">model.frame</a> ) containing the variables in the formula formula. By default the variables are taken from <code>environment(formula)</code> .                                                                                                                                              |
| subset    | an optional vector used to select rows (observations) of the data matrix x.                                                                                                                                                                                                                                                                     |
| na.action | a function which indicates what should happen when the data contain NAs. The default is set by the <code>na.action</code> setting of <a href="#">options</a> , and is <a href="#">na.fail</a> if that is unset. The ‘factory-fresh’ default is <a href="#">na.omit</a> .                                                                        |
| x         | a numeric matrix or data frame which provides the data for the principal components analysis.                                                                                                                                                                                                                                                   |
| cor       | a logical value indicating whether the calculation should use the correlation matrix or the covariance matrix. (The correlation matrix can only be used if there are no constant variables.)                                                                                                                                                    |
| scores    | a logical value indicating whether the score on each principal component should be calculated.                                                                                                                                                                                                                                                  |
| covmat    | a covariance matrix, or a covariance list as returned by <a href="#">cov.wt</a> (and <a href="#">cov.mve</a> or <a href="#">cov.mcd</a> from package <b>MASS</b> ). If supplied, this is used rather than the covariance matrix of x.                                                                                                           |
| fix_sign  | Should the signs of the loadings and scores be chosen so that the first element of each loading is non-negative?                                                                                                                                                                                                                                |
| ...       | arguments passed to or from other methods. If x is a formula one might specify <code>cor</code> or <code>scores</code> .                                                                                                                                                                                                                        |
| object    | Object of class inheriting from "princomp".                                                                                                                                                                                                                                                                                                     |
| newdata   | An optional data frame or matrix in which to look for variables with which to predict. If omitted, the scores are used. If the original fit used a formula or a data frame or a matrix with column names, newdata must contain columns with the same names. Otherwise it must contain the same number of columns, to be used in the same order. |

**Details**

`princomp` is a generic function with "formula" and "default" methods.

The calculation is done using [eigen](#) on the correlation or covariance matrix, as determined by `cor`. (This was done for compatibility with the S-PLUS result.) A preferred method of calculation is to use [svd](#) on x, as is done in `prcomp`.

Note that the default calculation uses divisor N for the covariance matrix.

The `print` method for these objects prints the results in a nice format and the `plot` method produces a scree plot (`screeplot`). There is also a `biplot` method.

If `x` is a formula then the standard NA-handling is applied to the scores (if requested): see `napredict`.

`princomp` only handles so-called R-mode PCA, that is feature extraction of variables. If a data matrix is supplied (possibly via a formula) it is required that there are at least as many units as variables. For Q-mode PCA use `prcomp`.

## Value

`princomp` returns a list with class "princomp" containing the following components:

|                        |                                                                                                                                                                                                                                                                                                                                                                      |
|------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>sdev</code>      | the standard deviations of the principal components.                                                                                                                                                                                                                                                                                                                 |
| <code>loadings</code>  | the matrix of variable loadings (i.e., a matrix whose columns contain the eigenvectors). This is of class "loadings": see <code>loadings</code> for its print method.                                                                                                                                                                                                |
| <code>center</code>    | the means that were subtracted.                                                                                                                                                                                                                                                                                                                                      |
| <code>scale</code>     | the scalings applied to each variable.                                                                                                                                                                                                                                                                                                                               |
| <code>n.obs</code>     | the number of observations.                                                                                                                                                                                                                                                                                                                                          |
| <code>scores</code>    | if <code>scores = TRUE</code> , the scores of the supplied data on the principal components. These are non-null only if <code>x</code> was supplied, and if <code>covmat</code> was also supplied if it was a covariance list. For the formula method, <code>napredict()</code> is applied to handle the treatment of values omitted by the <code>na.action</code> . |
| <code>call</code>      | the matched call.                                                                                                                                                                                                                                                                                                                                                    |
| <code>na.action</code> | If relevant.                                                                                                                                                                                                                                                                                                                                                         |

## Note

The signs of the columns of the loadings and scores are arbitrary, and so may differ between different programs for PCA, and even between different builds of R: `fix_sign = TRUE` alleviates that.

print.power.htest

---

*Print Methods for Hypothesis Tests and Power Calculation Objects*

---

## Description

Printing objects of class "htest" or "power.htest", respectively, by simple [print](#) methods.

## Usage

```

## S3 method for class 'htest'
print(x, digits = getOption("digits"), prefix = "\t", ...)

## S3 method for class 'power.htest'
print(x, digits = getOption("digits"), ...)

```

## Arguments

|        |                                                                                                    |
|--------|----------------------------------------------------------------------------------------------------|
| x      | object of class "htest" or "power.htest".                                                          |
| digits | number of significant digits to be used.                                                           |
| prefix | string, passed to <a href="#">strwrap</a> for displaying the method component of the htest object. |
| ...    | further arguments to be passed to or from methods.                                                 |

## Details

Both [print](#) methods traditionally have not obeyed the digits argument properly. They now do, the htest method mostly in expressions like `max(1, digits - 2)`.

A power.htest object is just a named list of numbers and character strings, supplemented with method and note elements. The method is displayed as a title, the note as a footnote, and the remaining elements are given in an aligned 'name = value' format.

**Value**

the argument `x`, invisibly, as for all [print](#) methods.

**Author(s)**

Peter Dalgaard

**See Also**

[power.t.test](#), [power.prop.test](#)

**Examples**

```
(ptt <- power.t.test(n = 20, delta = 1))
print(ptt, digits = 4) # using less digits than default
print(ptt, digits = 12) # using more " " "
```

---

print.ts

---

*Printing and Formatting of Time-Series Objects*

---

**Description**

Notably for calendar related time series objects, [format](#) and [print](#) methods showing years, months and or quarters respectively.

**Usage**

```
## S3 method for class 'ts'
print(x, calendar, ...)
.preformat.ts(x, calendar, ...)
```

**Arguments**

|                       |                                                                                                                                                                    |
|-----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>        | a time series object.                                                                                                                                              |
| <code>calendar</code> | enable/disable the display of information about month names, quarter names or year when printing. The default is TRUE for a frequency of 4 or 12, FALSE otherwise. |
| <code>...</code>      | additional arguments to <a href="#">print</a> (or <a href="#">format</a> methods).                                                                                 |

**Details**

The [print](#) method for "ts" objects prints a header (basically of [tsp\(x\)](#)), if `calendar` is false, and then prints the result of `.preformat.ts(x, *)`, which is typically a [matrix](#) with [rownames](#) built from the calendar times where applicable.

**See Also**

[print](#), [ts](#).

## Examples

```
print(ts(1:10, frequency = 7, start = c(12, 2)), calendar = TRUE)

print(sunsp.1 <- window(sunspot.m2014, end=c(1756, 12)))
m <- .preformat.ts(sunsp.1) # a character matrix
```

---

|              |                                   |
|--------------|-----------------------------------|
| printCoefmat | <i>Print Coefficient Matrices</i> |
|--------------|-----------------------------------|

---

## Description

Utility function to be used in higher-level [print](#) methods, such as those for [summary.lm](#), [summary.glm](#) and [anova](#). The goal is to provide a flexible interface with smart defaults such that often, only `x` needs to be specified.

## Usage

```
printCoefmat(x, digits = max(3, getOption("digits") - 2),
             signif.stars = getOption("show.signif.stars"),
             signif.legend = signif.stars,
             dig.tst = max(1, min(5, digits - 1)),
             cs.ind = 1L:k, tst.ind = k + 1L,
             zap.ind = integer(), P.values = NULL,
             has.Pvalue = nc >= 4L && length(cn <- colnames(x)) &&
               substr(cn[nc], 1L, 3L) %in% c("Pr(", "p-v"),
             eps.Pvalue = .Machine$double.eps,
             na.print = "NA", quote = FALSE, right = TRUE, ...)
```

## Arguments

|                            |                                                                                                                                                                                                                                                                                                                                                                          |
|----------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>             | a numeric matrix like object, to be printed.                                                                                                                                                                                                                                                                                                                             |
| <code>digits</code>        | minimum number of significant digits to be used for most numbers.                                                                                                                                                                                                                                                                                                        |
| <code>signif.stars</code>  | logical; if TRUE, P-values are additionally encoded visually as ‘significance stars’ in order to help scanning of long coefficient tables. It defaults to the <code>show.signif.stars</code> slot of <a href="#">options</a> .                                                                                                                                           |
| <code>signif.legend</code> | logical; if TRUE, a legend for the ‘significance stars’ is printed provided <code>signif.stars = TRUE</code> .                                                                                                                                                                                                                                                           |
| <code>dig.tst</code>       | minimum number of significant digits for the test statistics, see <code>tst.ind</code> .                                                                                                                                                                                                                                                                                 |
| <code>cs.ind</code>        | indices (integer) of column numbers which are (like) coefficients and standard errors to be formatted together.                                                                                                                                                                                                                                                          |
| <code>tst.ind</code>       | indices (integer) of column numbers for test statistics.                                                                                                                                                                                                                                                                                                                 |
| <code>zap.ind</code>       | indices (integer) of column numbers which should be formatted by <a href="#">zapsmall</a> , i.e., by ‘zapping’ values close to 0.                                                                                                                                                                                                                                        |
| <code>P.values</code>      | logical or NULL; if TRUE, the last column of <code>x</code> is formatted by <a href="#">format.pval</a> as P values. If <code>P.values = NULL</code> , the default, it is set to TRUE only if <a href="#">options</a> ("show.coef.Pvalue") is TRUE <i>and</i> <code>x</code> has at least 4 columns <i>and</i> the last column name of <code>x</code> starts with "Pr(". |

`has.Pvalue` logical; if TRUE, the last column of `x` contains P values; in that case, it is printed if and only if `P.values` (above) is true.

`eps.Pvalue` number, passed to `format.pval()` as `eps`.

`na.print` a character string to code NA values in printed output.

`quote, right, ...` further arguments passed to `print.default`.

**Value**

Invisibly returns its argument, `x`.

**Author(s)**

Martin Maechler

**See Also**

`print.summary.lm`, `format.pval`, `format`.

**Examples**

```
cmat <- cbind(rnorm(3, 10), sqrt(rchisq(3, 12)))
cmat <- cbind(cmat, cmat[, 1]/cmat[, 2])
cmat <- cbind(cmat, 2*pnorm(-cmat[, 3]))
colnames(cmat) <- c("Estimate", "Std.Err", "Z value", "Pr(>z)")
printCoefmat(cmat[, 1:3])
printCoefmat(cmat)
op <- options(show.coef.Pvalues = FALSE)
printCoefmat(cmat, digits = 2)
printCoefmat(cmat, digits = 2, P.values = TRUE)
options(op) # restore
```

---

profile

*Generic Function for Profiling Models*

---

**Description**

Investigates the behavior of the objective function near the solution represented by `fitted`.  
See documentation on method functions for further details.

**Usage**

```
profile(fitted, ...)
```

**Arguments**

`fitted` the original fitted model object.

`...` additional parameters. See documentation on individual methods.

**Value**

A list with an element for each parameter being profiled. See the individual methods for further details.

**See Also**

[profile.nls](#), [profile.glm](#)...

[plot.profile](#).

For profiling R code, see [Rprof](#).

---

profile.glm

*Method for Profiling glm Objects*

---

**Description**

Investigates the profile log-likelihood function for a fitted model of class "glm".

**Usage**

```
## S3 method for class 'glm'
profile(fitted, which = 1:p, alpha = 0.01, maxsteps = 10,
       del = zmax/5, trace = FALSE, test = c("LRT", "Rao"), ...)
```

**Arguments**

|          |                                                                                                                                             |
|----------|---------------------------------------------------------------------------------------------------------------------------------------------|
| fitted   | the original fitted model object.                                                                                                           |
| which    | the original model parameters which should be profiled. This can be a numeric or character vector. By default, all parameters are profiled. |
| alpha    | highest significance level allowed for the profile z-statistics.                                                                            |
| maxsteps | maximum number of points to be used for profiling each parameter.                                                                           |
| del      | suggested change on the scale of the profile t-statistics. Default value chosen to allow profiling at about 10 parameter values.            |
| trace    | logical: should the progress of profiling be reported?                                                                                      |
| test     | profile Likelihood Ratio test or Rao Score test.                                                                                            |
| ...      | further arguments passed to or from other methods.                                                                                          |

**Details**

The profile z-statistic is defined either as (case `test = "LRT"`) the square root of change in deviance with an appropriate sign, or (case `test = "Rao"`) as the similarly signed square root of the Rao Score test statistic. The latter is defined as the squared gradient of the profile log likelihood divided by the profile Fisher information, but more conveniently calculated via the deviance of a Gaussian GLM fitted to the residuals of the profiled model.

**Value**

A list of classes "profile.glm" and "profile" with an element for each parameter being profiled. The elements are data-frames with two variables

|          |                                                                                                         |
|----------|---------------------------------------------------------------------------------------------------------|
| par.vals | a matrix of parameter values for each fitted model.                                                     |
| tau or z | the profile t or z-statistics (the name depends on whether there is an estimated dispersion parameter.) |

**Author(s)**

Originally, D. M. Bates and W. N. Venables. (For S in 1996.)

**See Also**

[glm](#), [profile](#), [plot.profile](#)

**Examples**

```
options(contrasts = c("contr.treatment", "contr.poly"))
ldose <- rep(0:5, 2)
numdead <- c(1, 4, 9, 13, 18, 20, 0, 2, 6, 10, 12, 16)
sex <- factor(rep(c("M", "F"), c(6, 6)))
SF <- cbind(numdead, numalive = 20 - numdead)
budworm.lg <- glm(SF ~ sex*ldose, family = binomial)
pr1 <- profile(budworm.lg)
plot(pr1)
pairs(pr1)
```

---

profile.nls

---

*Method for Profiling nls Objects*

---

**Description**

Investigates the profile log-likelihood function for a fitted model of class "nls".

**Usage**

```
## S3 method for class 'nls'
profile(fitted, which = 1:npar, maxpts = 100, alphamax = 0.01,
        delta.t = cutoff/5, ...)
```

**Arguments**

|          |                                                                                                                                                        |
|----------|--------------------------------------------------------------------------------------------------------------------------------------------------------|
| fitted   | the original fitted model object.                                                                                                                      |
| which    | the original model parameters which should be profiled. This can be a numeric or character vector. By default, all non-linear parameters are profiled. |
| maxpts   | maximum number of points to be used for profiling each parameter.                                                                                      |
| alphamax | highest significance level allowed for the profile t-statistics.                                                                                       |
| delta.t  | suggested change on the scale of the profile t-statistics. Default value chosen to allow profiling at about 10 parameter values.                       |
| ...      | further arguments passed to or from other methods.                                                                                                     |

**Details**

The profile t-statistics is defined as the square root of change in sum-of-squares divided by residual standard error with an appropriate sign.

**Value**

A list with an element for each parameter being profiled. The elements are data-frames with two variables

`par.vals`            a matrix of parameter values for each fitted model.  
`tau`                the profile t-statistics.

**Author(s)**

Of the original version, Douglas M. Bates and Saikat DebRoy

**Examples**

```
# obtain the fitted object
fm1 <- nls(demand ~ SSasymptOrig(Time, A, lrc), data = BOD)
# get the profile for the fitted model: default level is too extreme
pr1 <- profile(fm1, alphamax = 0.05)
# profiled values for the two parameters

pr1$A
pr1$lrc

# see also example(plot.profile.nls)
```

---

proj

*Projections of Models*

---

**Description**

`proj` returns a matrix or list of matrices giving the projections of the data onto the terms of a linear model. It is most frequently used for [aov](#) models.

**Usage**

```
proj(object, ...)
```

## S3 method for class 'aov'

```
proj(object, onedf = FALSE, unweighted.scale = FALSE, ...)
```

## S3 method for class 'aovlist'

```
proj(object, onedf = FALSE, unweighted.scale = FALSE, ...)
```

```
## Default S3 method:
proj(object, onedf = TRUE, ...)

## S3 method for class 'lm'
proj(object, onedf = FALSE, unweighted.scale = FALSE, ...)
```

### Arguments

|                  |                                                                                                                                                                                                                            |
|------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| object           | An object of class "lm" or a class inheriting from it, or an object with a similar structure including in particular components qr and effects.                                                                            |
| onedf            | A logical flag. If TRUE, a projection is returned for all the columns of the model matrix. If FALSE, the single-column projections are collapsed by terms of the model (as represented in the analysis of variance table). |
| unweighted.scale | If the fit producing object used weights, this determines if the projections correspond to weighted or unweighted observations.                                                                                            |
| ...              | Swallow and ignore any other arguments.                                                                                                                                                                                    |

### Details

A projection is given for each stratum of the object, so for aov models with an Error term the result is a list of projections.

### Value

A projection matrix or (for multi-stratum objects) a list of projection matrices.

Each projection is a matrix with a row for each observations and either a column for each term (onedf = FALSE) or for each coefficient (onedf = TRUE). Projection matrices from the default method have orthogonal columns representing the projection of the response onto the column space of the Q matrix from the QR decomposition. The fitted values are the sum of the projections, and the sum of squares for each column is the reduction in sum of squares from fitting that column (after those to the left of it).

The methods for lm and aov models add a column to the projection matrix giving the residuals (the projection of the data onto the orthogonal complement of the model space).

Strictly, when onedf = FALSE the result is not a projection, but the columns represent sums of projections onto the columns of the model matrix corresponding to that term. In this case the matrix does not depend on the coding used.

### Author(s)

The design was inspired by the S function of the same name described in Chambers et al. (1992).

|           |                                           |
|-----------|-------------------------------------------|
| prop.test | <i>Test of Equal or Given Proportions</i> |
|-----------|-------------------------------------------|

---

Description

prop.test can be used for testing the null that the proportions (probabilities of success) in several groups are the same, or that they equal certain given values.

Usage

```
prop.test(x, n, p = NULL,
          alternative = c("two.sided", "less", "greater"),
          conf.level = 0.95, correct = TRUE)
```

Arguments

|             |                                                                                                                                                                                                                                                                                                   |
|-------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| x           | a vector of counts of successes, a one-dimensional table with two entries, or a two-dimensional table (or matrix) with 2 columns, giving the counts of successes and failures, respectively.                                                                                                      |
| n           | a vector of counts of trials; ignored if x is a matrix or a table.                                                                                                                                                                                                                                |
| p           | a vector of probabilities of success. The length of p must be the same as the number of groups specified by x, and its elements must be greater than 0 and less than 1.                                                                                                                           |
| alternative | a character string specifying the alternative hypothesis, must be one of "two.sided" (default), "greater" or "less". You can specify just the initial letter. Only used for testing the null that a single proportion equals a given value, or that two proportions are equal; ignored otherwise. |
| conf.level  | confidence level of the returned confidence interval. Must be a single number between 0 and 1. Only used when testing the null that a single proportion equals a given value, or that two proportions are equal; ignored otherwise.                                                               |
| correct     | a logical indicating whether Yates' continuity correction should be applied where possible.                                                                                                                                                                                                       |

## Details

Only groups with finite numbers of successes and failures are used. Counts of successes and failures must be nonnegative and hence not greater than the corresponding numbers of trials which must be positive. All finite counts should be integers.

If `p` is `NULL` and there is more than one group, the null tested is that the proportions in each group are the same. If there are two groups, the alternatives are that the probability of success in the first group is less than, not equal to, or greater than the probability of success in the second group, as specified by `alternative`. A confidence interval for the difference of proportions with confidence level as specified by `conf.level` and clipped to  $[-1, 1]$  is returned. Continuity correction is used only if it does not exceed the difference of the sample proportions in absolute value. Otherwise, if there are more than 2 groups, the alternative is always "two.sided", the returned confidence interval is `NULL`, and continuity correction is never used.

If there is only one group, then the null tested is that the underlying probability of success is `p`, or `.5` if `p` is not given. The alternative is that the probability of success is less than, not equal to, or greater than `p` or `0.5`, respectively, as specified by `alternative`. A confidence interval for the underlying proportion with confidence level as specified by `conf.level` and clipped to  $[0, 1]$  is returned. Continuity correction is used only if it does not exceed the difference between sample and null proportions in absolute value. The confidence interval is computed by inverting the score test.

Finally, if `p` is given and there are more than 2 groups, the null tested is that the underlying probabilities of success are those given by `p`. The alternative is always "two.sided", the returned confidence interval is `NULL`, and continuity correction is never used.

## Value

A list with class "htest" containing the following components:

|                          |                                                                                                                                                                                                                                                                                                                                                                                                                             |
|--------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>statistic</code>   | the value of Pearson's chi-squared test statistic.                                                                                                                                                                                                                                                                                                                                                                          |
| <code>parameter</code>   | the degrees of freedom of the approximate chi-squared distribution of the test statistic.                                                                                                                                                                                                                                                                                                                                   |
| <code>p.value</code>     | the p-value of the test.                                                                                                                                                                                                                                                                                                                                                                                                    |
| <code>estimate</code>    | a vector with the sample proportions $x/n$ .                                                                                                                                                                                                                                                                                                                                                                                |
| <code>conf.int</code>    | a confidence interval for the true proportion if there is one group, or for the difference in proportions if there are 2 groups and <code>p</code> is not given, or <code>NULL</code> otherwise. In the cases where it is not <code>NULL</code> , the returned confidence interval has an asymptotic confidence level as specified by <code>conf.level</code> , and is appropriate to the specified alternative hypothesis. |
| <code>null.value</code>  | the value of <code>p</code> if specified by the null, or <code>NULL</code> otherwise.                                                                                                                                                                                                                                                                                                                                       |
| <code>alternative</code> | a character string describing the alternative.                                                                                                                                                                                                                                                                                                                                                                              |
| <code>method</code>      | a character string indicating the method used, and whether Yates' continuity correction was applied.                                                                                                                                                                                                                                                                                                                        |
| <code>data.name</code>   | a character string giving the names of the data.                                                                                                                                                                                                                                                                                                                                                                            |

|-----------------|--------------------------------------|
| prop.trend.test | <i>Test for trend in proportions</i> |
|-----------------|--------------------------------------|

---

### Description

Performs chi-squared test for trend in proportions, i.e., a test asymptotically optimal for local alternatives where the log odds vary in proportion with score. By default, score is chosen as the group numbers.

### Usage

```
prop.trend.test(x, n, score = seq_along(x))
```

### Arguments

|       |                  |
|-------|------------------|
| x     | Number of events |
| n     | Number of trials |
| score | Group score      |

### Value

An object of class "htest" with title, test statistic, p-value, etc.

### Note

This really should get integrated with prop.test

## Arguments

|                               |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|-------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>                | The first sample for qqplot.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <code>y</code>                | The second or only data sample.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <code>xlab, ylab, main</code> | plot labels. The <code>xlab</code> and <code>ylab</code> refer to the y and x axes respectively if <code>datax = TRUE</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <code>plot.it</code>          | logical. Should the result be plotted?                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <code>datax</code>            | logical. Should data values be on the x-axis?                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <code>distribution</code>     | quantile function for reference theoretical distribution.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <code>probs</code>            | numeric vector of length two, representing probabilities. Corresponding quantile pairs define the line drawn.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <code>qtype</code>            | the type of quantile computation used in <a href="#">quantile</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <code>ylim, ...</code>        | graphical parameters.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <code>conf.level</code>       | confidence level of the band. The default, <code>NULL</code> , does not lead to the computation of a confidence band.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <code>conf.args</code>        | list of arguments defining confidence band computation and visualisation: <code>exact</code> is <code>NULL</code> (see details) or a logical indicating whether an exact p-value should be computed, <code>simulate.p.value</code> is a logical indicating whether to compute p-values by Monte Carlo simulation, <code>B</code> defines the number of replicates used in the Monte Carlo test, <code>col</code> and <code>border</code> define the color for filling and border of the confidence band (the default, <code>NA</code> and <code>NULL</code> , is to leave the band unfilled with black borders). |

## Value

For `qqnorm` and `qqplot`, a list with components

|                |                                                                                                                                                                                                                                                                   |
|----------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code> | The x coordinates of the points that were/would be plotted                                                                                                                                                                                                        |
| <code>y</code> | The original y vector, i.e., the corresponding y coordinates <i>including NAs</i> . If <code>conf.level</code> was specified to <code>qqplot</code> , the list contains additional components <code>lwr</code> and <code>upr</code> defining the confidence band. |

[ppoints](#), used by `qqnorm` to generate approximations to expected order statistics for a normal distribution.

## Examples

```
require(graphics)

y <- rt(200, df = 5)
qqnorm(y); qqline(y, col = 2)
qqplot(y, rt(300, df = 5))
```

```

qqnorm(precip, ylab = "Precipitation [in/yr] for 70 US cities")

## "QQ-Chisquare" : -----
y <- rchisq(500, df = 3)
## Q-Q plot for Chi^2 data against true theoretical distribution:
qqplot(qchisq(ppoints(500), df = 3), y,
       main = expression("Q-Q plot for" ~{chi^2}[nu == 3]))
qqline(y, distribution = function(p) qchisq(p, df = 3),
       probs = c(0.1, 0.6), col = 2)
mtext("qqline(*, dist = qchisq(., df=3), prob = c(0.1, 0.6))")
## (Note that the above uses ppoints() with a = 1/2, giving the
## probability points for quantile type 5: so theoretically, using
## qqline(qtype = 5) might be preferable.)

quade.test

*Quade Test***Description**

Performs a Quade test with unreplicated blocked data.

**Usage**

```
quade.test(y, ...)

## Default S3 method:
quade.test(y, groups, blocks, ...)

## S3 method for class 'formula'
quade.test(formula, data, subset, na.action, ...)
```

**Arguments**

|                        |                                                                                                                                                                                                                            |
|------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>y</code>         | either a numeric vector of data values, or a data matrix.                                                                                                                                                                  |
| <code>groups</code>    | a vector giving the group for the corresponding elements of <code>y</code> if this is a vector; ignored if <code>y</code> is a matrix. If not a factor object, it is coerced to one.                                       |
| <code>blocks</code>    | a vector giving the block for the corresponding elements of <code>y</code> if this is a vector; ignored if <code>y</code> is a matrix. If not a factor object, it is coerced to one.                                       |
| <code>formula</code>   | a formula of the form <code>a ~ b   c</code> , where <code>a</code> , <code>b</code> and <code>c</code> give the data values and corresponding groups and blocks, respectively.                                            |
| <code>data</code>      | an optional matrix or data frame (or similar: see <a href="#">model.frame</a> ) containing the variables in the formula <code>formula</code> . By default the variables are taken from <code>environment(formula)</code> . |
| <code>subset</code>    | an optional vector specifying a subset of observations to be used.                                                                                                                                                         |
| <code>na.action</code> | a function which indicates what should happen when the data contain NAs. Defaults to <code>getOption("na.action")</code> .                                                                                                 |
| <code>...</code>       | further arguments to be passed to or from methods.                                                                                                                                                                         |

**Details**

`quade.test` can be used for analyzing unreplicated complete block designs (i.e., there is exactly one observation in `y` for each combination of levels of groups and blocks) where the normality assumption may be violated.

The null hypothesis is that apart from an effect of blocks, the location parameter of `y` is the same in each of the groups.

If `y` is a matrix, `groups` and `blocks` are obtained from the column and row indices, respectively. NA's are not allowed in `groups` or `blocks`; if `y` contains NA's, corresponding blocks are removed.

**Value**

A list with class `"htest"` containing the following components:

|                        |                                                                                                                         |
|------------------------|-------------------------------------------------------------------------------------------------------------------------|
| <code>statistic</code> | the value of Quade's F statistic.                                                                                       |
| <code>parameter</code> | a vector with the numerator and denominator degrees of freedom of the approximate F distribution of the test statistic. |
| <code>p.value</code>   | the p-value of the test.                                                                                                |
| <code>method</code>    | the character string <code>"Quade test"</code> .                                                                        |
| <code>data.name</code> | a character string giving the names of the data.                                                                        |

---

quantile

*Sample Quantiles*

---

## Description

The generic function `quantile` produces sample quantiles corresponding to the given probabilities. The smallest observation corresponds to a probability of 0 and the largest to a probability of 1.

## Usage

```
quantile(x, ...)
```

## Default S3 method:

```
quantile(x, probs = seq(0, 1, 0.25), na.rm = FALSE,
```

```
names = TRUE, type = 7, digits = 7,
fuzz = if(type == 7L) 0 else 4 * .Machine$double.eps,
...)
```

### Arguments

|                     |                                                                                                                                                                                                                                                                     |
|---------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>      | numeric vector whose sample quantiles are wanted, or an object of a class for which a method has been defined (see also ‘details’). <code>NA</code> and <code>NaN</code> values are not allowed in numeric vectors unless <code>na.rm</code> is <code>TRUE</code> . |
| <code>probs</code>  | numeric vector of probabilities with values in $[0, 1]$ . (Values up to ‘2e-14’ outside that range are accepted and moved to the nearby endpoint.)                                                                                                                  |
| <code>na.rm</code>  | logical; if true, any <code>NA</code> and <code>NaN</code> ’s are removed from <code>x</code> before the quantiles are computed.                                                                                                                                    |
| <code>names</code>  | logical; if true, the result has a <code>names</code> attribute. Set to <code>FALSE</code> for speedup with many <code>probs</code> .                                                                                                                               |
| <code>type</code>   | an integer between 1 and 9 selecting one of the nine quantile algorithms detailed below to be used.                                                                                                                                                                 |
| <code>digits</code> | used only when <code>names</code> is true: the precision to use when formatting the percentages. In R versions up to 4.0.x, this had been set to <code>max(2, getOption("digits"))</code> , internally.                                                             |
| <code>fuzz</code>   | small non-negative number to protect against rounding errors when <code>j &lt;- floor(np + m)</code> , ( <code>np</code> “a version of” <code>n * probs</code> , see the formula below), is computed.                                                               |
| <code>...</code>    | further arguments passed to or from other methods.                                                                                                                                                                                                                  |

### Details

A vector of length `length(probs)` is returned; if `names = TRUE`, it has a `names` attribute.

`NA` and `NaN` values in `probs` are propagated to the result.

The default method works with classed objects sufficiently like numeric vectors that `sort` and (not needed by types 1 and 3) addition of elements and multiplication by a number work correctly. Note that as this is in a namespace, the copy of `sort` in **base** will be used, not some S4 generic of that name. Also note that that is no check on the ‘correctly’, and so e.g. `quantile` can be applied to complex vectors which (apart from ties) will be ordered on their real parts.

There is a method for the date-time classes (see “[POSIXt](#)”). Types 1 and 3 can be used for class “[Date](#)” and for ordered factors.

`fuzz := 4 * .Machine$double.eps` has been hard coded and used for `type = 4, 5, 6, 8, 9` since types were introduced, and is used, since R 4.5.0, also for the other types (but with default 0 for the default `type = 7` for back compatibility reasons).

### Types

`quantile` returns estimates of underlying distribution quantiles based on one or two order statistics from the supplied elements in `x` at probabilities in `probs`. One of the nine quantile algorithms discussed in Hyndman and Fan (1996), selected by `type`, is employed.

All sample quantiles are defined as weighted averages of consecutive order statistics. Sample quantiles of type  $i$  are defined by:

$$Q_i(p) = (1 - \gamma)x_j + \gamma x_{j+1}$$

where  $1 \leq i \leq 9$ ,  $\frac{j-m}{n} \leq p < \frac{j-m+1}{n}$ ,  $x_j$  is the  $j$ -th order statistic,  $n$  is the sample size, the value of  $\gamma$  is a function of  $j = \lfloor np + m \rfloor$  and  $g = np + m - j$ , and  $m$  is a constant determined by the sample quantile type.

#### Discontinuous sample quantile types 1, 2, and 3:

For types 1, 2 and 3,  $Q_i(p)$  is a discontinuous function of  $p$ , with  $m = 0$  when  $i = 1$  and  $i = 2$ , and  $m = -1/2$  when  $i = 3$ .

**Type 1** Inverse of empirical distribution function.  $\gamma = 0$  if  $g = 0$ , and 1 otherwise.

**Type 2** Similar to type 1 but with averaging at discontinuities.  $\gamma = 0.5$  if  $g = 0$ , and 1 otherwise (SAS default, see Wicklin (2017)).

**Type 3** Nearest even order statistic (SAS default till ca. 2010).  $\gamma = 0$  if  $g = 0$  and  $j$  is even, and 1 otherwise.

#### Continuous sample quantile types 4 through 9:

For types 4 through 9,  $Q_i(p)$  is a continuous function of  $p$ , with  $\gamma = g$  and  $m$  given below. The sample quantiles can be obtained equivalently by linear interpolation between the points  $(p_k, x_k)$  where  $x_k$  is the  $k$ -th order statistic. Specific expressions for  $p_k$  are given below.

**Type 4**  $m = 0$ .  $p_k = \frac{k}{n}$ . That is, linear interpolation of the empirical cdf.

**Type 5**  $m = 1/2$ .  $p_k = \frac{k-0.5}{n}$ . That is a piecewise linear function where the knots are the values midway through the steps of the empirical cdf. This is popular amongst hydrologists.

**Type 6**  $m = p$ .  $p_k = \frac{k}{n+1}$ . Thus  $p_k = E[F(x_k)]$ . This is used by Minitab and by SPSS.

**Type 7**  $m = 1 - p$ .  $p_k = \frac{k-1}{n-1}$ . In this case,  $p_k = \text{mode}[F(x_k)]$ . This is used by S.

**Type 8**  $m = (p + 1)/3$ .  $p_k = \frac{k-1/3}{n+1/3}$ . Then  $p_k \approx \text{median}[F(x_k)]$ . The resulting quantile estimates are approximately median-unbiased regardless of the distribution of  $x$ .

**Type 9**  $m = p/4 + 3/8$ .  $p_k = \frac{k-3/8}{n+1/4}$ . The resulting quantile estimates are approximately unbiased for the expected order statistics if  $x$  is normally distributed.

Further details are provided in Hyndman and Fan (1996) who recommended type 8. The default method is type 7, as used by S and by R < 2.0.0. Makkonen and Pajari (2014) argue for type 6, also as already proposed by Weibull in 1939. The Wikipedia page contains further information about availability of these 9 types in software.

#### Author(s)

of the version used in R >= 2.0.0, Ivan Frohne and Rob J Hyndman; tweaks, notably use of fuzz, by the R Core Team.

|----------|-------------------------------------------------|
| r2dtable | <i>Random 2-way Tables with Given Marginals</i> |
|----------|-------------------------------------------------|

---

Description

Generate random 2-way tables with given marginals using Patefield’s algorithm.

Usage

```
r2dtable(n, r, c)
```

Arguments

- n                    a non-negative numeric giving the number of tables to be drawn.
- r                    a non-negative vector of length at least 2 giving the row totals, to be coerced to integer. Must sum to the same as c.
- c                    a non-negative vector of length at least 2 giving the column totals, to be coerced to integer.

Value

A list of length n containing the generated tables as its components.

References

Patefield, W. M. (1981). Algorithm AS 159: An efficient method of generating  $r \times c$  tables with given row and column totals. *Applied Statistics*, **30**, 91–97. doi:10.2307/2346669.

## Examples

```
## Fisher's Tea Drinker data.
TeaTasting <-
matrix(c(3, 1, 1, 3),
       nrow = 2,
       dimnames = list(Guess = c("Milk", "Tea"),
                        Truth = c("Milk", "Tea")))
## Simulate permutation test for independence based on the maximum
## Pearson residuals (rather than their sum).
rowTotals <- rowSums(TeaTasting)
colTotals <- colSums(TeaTasting)
nOfCases <- sum(rowTotals)
expected <- outer(rowTotals, colTotals) / nOfCases
maxSqResid <- function(x) max((x - expected) ^ 2 / expected)
simMaxSqResid <-
  sapply(r2dtable(1000, rowTotals, colTotals), maxSqResid)
sum(simMaxSqResid >= maxSqResid(TeaTasting)) / 1000
## Fisher's exact test gives p = 0.4857 ...
```

---

read.ftable

---

*Manipulate Flat Contingency Tables*

---

## Description

Read, write and coerce ‘flat’ (contingency) tables, aka ftables.

## Usage

```
read.ftable(file, sep = "", quote = "\"",
            row.var.names, col.vars, skip = 0)

write.ftable(x, file = "", quote = TRUE, append = FALSE,
            digits = getOption("digits"), sep = " ", ...)

## S3 method for class 'ftable'
format(x, quote = TRUE, digits = getOption("digits"),
       method = c("non.compact", "row.compact", "col.compact", "compact"),
       lsep = " | ",
       justify = c("left", "right"),
       ...)

## S3 method for class 'ftable'
print(x, digits = getOption("digits"), ...)
```

## Arguments

|      |                                                                                                                                                                                                                  |
|------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| file | either a character string naming a file or a <a href="#">connection</a> which the data are to be read from or written to. "" indicates input from the console for reading and output to the console for writing. |
| sep  | the field separator string. Values on each line of the file are separated by this string.                                                                                                                        |

|               |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|---------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| quote         | a character string giving the set of quoting characters for read.ftable; to disable quoting altogether, use quote="". For write.table, a logical indicating whether strings in the data will be surrounded by double quotes.                                                                                                                                                                                                                                                                                                                                                                                                     |
| row.var.names | a character vector with the names of the row variables, in case these cannot be determined automatically.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| col.vars      | a list giving the names and levels of the column variables, in case these cannot be determined automatically.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| skip          | the number of lines of the data file to skip before beginning to read data.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| x             | an object of class "ftable".                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| append        | logical. If TRUE and file is the name of a file (and not a connection or " cmd"), the output from write.ftable is appended to the file. If FALSE, the contents of file will be overwritten.                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| digits        | an integer giving the number of significant digits to use for (the cell entries of) x.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| method        | string specifying how the "ftable" object is formatted (and printed if used as in write.ftable() or the print method). Can be abbreviated. Available methods are (see the examples):<br><b>"non.compact"</b> the default representation of an "ftable" object.<br><b>"row.compact"</b> a row-compact version without empty cells below the column labels.<br><b>"col.compact"</b> a column-compact version without empty cells to the right of the row labels.<br><b>"compact"</b> a row- and column-compact version. This may imply a row and a column label sharing the same cell. They are then separated by the string lsep. |
| lsep          | only for method = "compact", the separation string for row and column labels.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| justify       | <a href="#">character</a> vector of length (one or) two, specifying how string justification should happen in format(.), first for the labels, then the table entries.                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| ...           | further arguments to be passed to or from methods; for write() and print(), notably arguments such as method, passed to format().                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

## Details

read.ftable reads in a flat-like contingency table from a file. If the file contains the written representation of a flat table (more precisely, a header with all information on names and levels of column variables, followed by a line with the names of the row variables), no further arguments are needed. Similarly, flat tables with only one column variable the name of which is the only entry in the first line are handled automatically. Other variants can be dealt with by skipping all header information using skip, and providing the names of the row variables and the names and levels of the column variable using row.var.names and col.vars, respectively. See the examples below.

Note that flat tables are characterized by their ‘ragged’ display of row (and maybe also column) labels. If the full grid of levels of the row variables is given, one should instead use [read.table](#) to read in the data, and create the contingency table from this using [xtabs](#).

write.ftable writes a flat table to a file, which is useful for generating ‘pretty’ ASCII representations of contingency tables. Different versions are available via the method argument, which may be useful, for example, for constructing LaTeX tables.

[ftable](#) for more information on flat contingency tables.

**Examples**

```
## Agresti (1990), page 157, Table 5.8.
## Not in ftable standard format, but o.k.
file <- tempfile()
cat("          Intercourse\n",
    "Race Gender      Yes No\n",
    "White Male        43 134\n",
    "      Female      26 149\n",
    "Black Male         29  23\n",
    "      Female       22  36\n",
    file = file)
file.show(file)
ft1 <- read.ftable(file)
ft1
unlink(file)

## Agresti (1990), page 297, Table 8.16.
## Almost o.k., but misses the name of the row variable.
file <- tempfile()
cat("          \"Tonsil Size\"\n",
    "          \"Not Enl.\" \"Enl.\" \"Greatly Enl.\"\n",
    "Noncarriers      497      560      269\n",
    "Carriers          19       29       24\n",
    file = file)
file.show(file)
ft <- read.ftable(file, skip = 2,
                  row.var.names = "Status",
                  col.vars = list("Tonsil Size" =
                                c("Not Enl.", "Enl.", "Greatly Enl.")))
ft
unlink(file)

ft22 <- ftable(Titanic, row.vars = 2:1, col.vars = 4:3)
write.ftable(ft22, quote = FALSE) # is the same as
print(ft22)#method="non.compact" is default
print(ft22, method="row.compact")
print(ft22, method="col.compact")
print(ft22, method="compact")

## using 'justify' and 'quote' :
format(ftable(wool + tension ~ breaks, warpbreaks),
       justify = "none", quote = FALSE)
```

rect.hclust

*Draw Rectangles Around Hierarchical Clusters***Description**

Draws rectangles around the branches of a dendrogram highlighting the corresponding clusters. First the dendrogram is cut at a certain level, then a rectangle is drawn around selected branches.

**Usage**

```
rect.hclust(tree, k = NULL, which = NULL, x = NULL, h = NULL,
            border = 2, cluster = NULL)
```

**Arguments**

|          |                                                                                                                                                                                                                                           |
|----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| tree     | an object of the type produced by <code>hclust</code> .                                                                                                                                                                                   |
| k, h     | Scalar. Cut the dendrogram such that either exactly k clusters are produced or by cutting at height h.                                                                                                                                    |
| which, x | A vector selecting the clusters around which a rectangle should be drawn. which selects clusters by number (from left to right in the tree), x selects clusters containing the respective horizontal coordinates. Default is which = 1:k. |
| border   | Vector with border colors for the rectangles.                                                                                                                                                                                             |
| cluster  | Optional vector with cluster memberships as returned by <code>cutree(hclust.obj, k = k)</code> , can be specified for efficiency if already computed.                                                                                     |

**Value**

(Invisibly) returns a list where each element contains a vector of data points contained in the respective cluster.

**See Also**

[hclust](#), [identify.hclust](#).

**Examples**

```
require(graphics)

hca <- hclust(dist(USArrests))
plot(hca)
rect.hclust(hca, k = 3, border = "red")
x <- rect.hclust(hca, h = 50, which = c(2,7), border = 3:4)
x
```

---

relevel

---

*Reorder Levels of Factor*

---

**Description**

The levels of a factor are re-ordered so that the level specified by `ref` is first and the others are moved down. This is useful for `contr.treatment` contrasts which take the first level as the reference.

**Usage**

```
relevel(x, ref, ...)
```

**Arguments**

|     |                                          |
|-----|------------------------------------------|
| x   | an unordered factor.                     |
| ref | the reference level, typically a string. |
| ... | additional arguments for future methods. |

Details

This, as `reorder()`, is a special case of simply calling `factor(x, levels = levels(x)[...])`.

Value

A factor of the same length as `x`.

See Also

`factor`, `contr.treatment`, `levels`, `reorder`.

Examples

```
warpbreaks$tension <- relevel(warpbreaks$tension, ref = "M")
summary(lm(breaks ~ wool + tension, data = warpbreaks))
```

---

|                 |                                   |
|-----------------|-----------------------------------|
| reorder.default | <i>Reorder Levels of a Factor</i> |
|-----------------|-----------------------------------|

---

Description

`reorder` is a generic function. The "default" method treats its first argument as a categorical variable, and reorders its levels based on the values of a second variable, usually numeric.

Usage

```
reorder(x, ...)

## Default S3 method:
reorder(x, X, FUN = mean, ...,
        order = is.ordered(x), decreasing = FALSE)
```

Arguments

- `x` an atomic vector, usually a `factor` (possibly ordered). The vector is treated as a categorical variable whose levels will be reordered. If `x` is not a factor, its unique values will be used as the implicit levels.
- `X` a vector of the same length as `x`, whose subset of values for each unique level of `x` determines the eventual order of that level.
- `FUN` a `function` whose first argument is a vector and returns a scalar, to be applied to each subset of `X` determined by the levels of `x`.
- `...` optional: extra arguments supplied to `FUN`
- `order` logical, whether return value will be an ordered factor rather than a factor.
- `decreasing` logical, whether the levels will be ordered in increasing or decreasing order.

Details

This, as `relevel()`, is a special case of simply calling `factor(x, levels = levels(x)[...])`.

**Value**

A factor or an ordered factor (depending on the value of `order`), with the order of the levels determined by `FUN` applied to `X` grouped by `x`. By default, the levels are ordered such that the values returned by `FUN` are in increasing order. Empty levels will be dropped.

Additionally, the values of `FUN` applied to the subsets of `X` (in the original order of the levels of `x`) is returned as the "scores" attribute.

**Examples**

```
require(graphics)

bymedian <- with(InsectSprays, reorder(spray, count, median))
boxplot(count ~ bymedian, data = InsectSprays,
        xlab = "Type of spray", ylab = "Insect count",
        main = "InsectSprays data", varwidth = TRUE,
        col = "lightgray")

bymedianR <- with(InsectSprays, reorder(spray, count, median, decreasing=TRUE))
stopifnot(exprs = {
  identical(attr(bymedian, "scores") -> sc,
            attr(bymedianR, "scores"))
  identical(nms <- names(sc), LETTERS[1:6])
  identical(levels(bymedian), nms[isc <- order(sc)])
  identical(levels(bymedianR), nms[rev(isc)])
})
```

---

|                    |                             |
|--------------------|-----------------------------|
| reorder.dendrogram | <i>Reorder a Dendrogram</i> |
|--------------------|-----------------------------|

---

**Description**

A method for the generic function [reorder](#).

There are many different orderings of a dendrogram that are consistent with the structure imposed. This function takes a dendrogram and a vector of values and reorders the dendrogram in the order of the supplied vector, maintaining the constraints on the dendrogram.

**Usage**

```
## S3 method for class 'dendrogram'
reorder(x, wts, agгло.FUN = sum, ...)
```

**Arguments**

|                        |                                                    |
|------------------------|----------------------------------------------------|
| <code>x</code>         | the (dendrogram) object to be reordered            |
| <code>wts</code>       | numeric weights (arbitrary values) for reordering. |
| <code>agglo.FUN</code> | a function for weights agglomeration, see below.   |
| <code>...</code>       | additional arguments                               |

**Details**

Using the weights `wts`, the leaves of the dendrogram are reordered so as to be in an order as consistent as possible with the weights. At each node, the branches are ordered in increasing weights where the weight of a branch is defined as  $f(w_j)$  where  $f$  is `agglo.FUN` and  $w_j$  is the weight of the  $j$ -th sub branch.

**Value**

A dendrogram where each node has a further attribute value with its corresponding weight.

**Author(s)**

R. Gentleman and M. Maechler

**See Also**

[reorder](#).

[rev.dendrogram](#) which simply reverses the nodes' order; [heatmap](#), [cophenetic](#).

**Examples**

```
require(graphics)

set.seed(123)
x <- rnorm(10)
hc <- hclust(dist(x))
dd <- as.dendrogram(hc)
dd.reorder <- reorder(dd, 10:1)
plot(dd, main = "random dendrogram 'dd'")

op <- par(mfcol = 1:2)
plot(dd.reorder, main = "reorder(dd, 10:1)")
plot(reorder(dd, 10:1, agglo.FUN = mean), main = "reorder(dd, 10:1, mean)")
par(op)
```

---

replications

*Number of Replications of Terms*

---

**Description**

Returns a vector or a list of the number of replicates for each term in the formula.

**Usage**

```
replications(formula, data = NULL, na.action)
```

**Arguments**

|           |                                                                                                                                                         |
|-----------|---------------------------------------------------------------------------------------------------------------------------------------------------------|
| formula   | a formula or a terms object or a data frame.                                                                                                            |
| data      | a data frame used to find the objects in formula.                                                                                                       |
| na.action | function for handling missing values. Defaults to a na.action attribute of data, then a setting of the option na.action, or na.fail if that is not set. |

**Details**

If formula is a data frame and data is missing, formula is used for data with the formula ~ ..

Any character vectors in the formula are coerced to factors.

**Value**

A vector or list with one entry for each term in the formula giving the number(s) of replications for each level. If all levels are balanced (have the same number of replications) the result is a vector, otherwise it is a list with a component for each terms, as a vector, matrix or array as required.

A test for balance is `!is.list(replications(formula,data))`.

**Author(s)**

The design was inspired by the S function of the same name described in Chambers et al. (1992).

## From Venables and Ripley (2002) p.165.
N <- c(0,1,0,1,1,1,0,0,0,1,1,0,1,1,0,0,1,0,1,0,1,1,0,0)
P <- c(1,1,0,0,0,1,0,1,1,1,0,0,0,1,0,1,1,0,0,1,0,1,1,0)
K <- c(1,0,0,1,0,1,1,0,0,1,0,1,0,1,1,0,0,0,1,1,1,0,1,0)
yield <- c(49.5,62.8,46.8,57.0,59.8,58.5,55.5,56.0,62.8,55.8,69.5,
55.0, 62.0,48.8,45.5,44.2,52.0,51.5,49.8,48.8,57.2,59.0,53.2,56.0)

npk <- data.frame(block = gl(6,4), N = factor(N), P = factor(P),
                  K = factor(K), yield = yield)
replications(~ . - yield, npk)
```

reshape

*Reshape Grouped Data***Description**

This function reshapes a data frame between ‘wide’ format (with repeated measurements in separate columns of the same row) and ‘long’ format (with the repeated measurements in separate rows).

**Usage**

```
reshape(data, varying = NULL, v.names = NULL, timevar = "time",
        idvar = "id", ids = 1:NROW(data),
        times = seq_along(varying[[1]]),
        drop = NULL, direction, new.row.names = NULL,
        sep = ".",
        split = if (sep == "") {
          list(regexp = "[A-Za-z][0-9]", include = TRUE)
        } else {
          list(regexp = sep, include = FALSE, fixed = TRUE)}
        )

### Typical usage for converting from long to wide format:

# reshape(data, direction = "wide",
#         idvar = "___", timevar = "___", # mandatory
#         v.names = c(___), # time-varying variables
#         varying = list(___)) # auto-generated if missing

### Typical usage for converting from wide to long format:

### If names of wide-format variables are in a 'nice' format

# reshape(data, direction = "long",
#         varying = c(___), # vector
#         sep) # to help guess 'v.names' and 'times'

### To specify long-format variable names explicitly

# reshape(data, direction = "long",
#         varying = ___, # list / matrix / vector (use with care)
#         v.names = ___, # vector of variable names in long format
#         timevar, times, # name / values of constructed time variable
#         idvar, ids) # name / values of constructed id variable
```

**Arguments**

|         |                                                                                                                                                                                                                                                      |
|---------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| data    | a data frame                                                                                                                                                                                                                                         |
| varying | names of sets of variables in the wide format that correspond to single variables in long format (‘time-varying’). This is canonically a list of vectors of variable names, but it can optionally be a matrix of names, or a single vector of names. |

|                            |                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|----------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                            | In each case, when <code>direction = "long"</code> , the names can be replaced by indices which are interpreted as referring to <code>names(data)</code> . See ‘Details’ for more details and options.                                                                                                                                                                                                                          |
| <code>v.names</code>       | names of variables in the long format that correspond to multiple variables in the wide format. See ‘Details’.                                                                                                                                                                                                                                                                                                                  |
| <code>timevar</code>       | the variable in long format that differentiates multiple records from the same group or individual. If more than one record matches, the first will be taken (with a warning).                                                                                                                                                                                                                                                  |
| <code>idvar</code>         | Names of one or more variables in long format that identify multiple records from the same group/individual. These variables may also be present in wide format.                                                                                                                                                                                                                                                                |
| <code>ids</code>           | the values to use for a newly created <code>idvar</code> variable in long format.                                                                                                                                                                                                                                                                                                                                               |
| <code>times</code>         | the values to use for a newly created <code>timevar</code> variable in long format. See ‘Details’.                                                                                                                                                                                                                                                                                                                              |
| <code>drop</code>          | a vector of names of variables to drop before reshaping.                                                                                                                                                                                                                                                                                                                                                                        |
| <code>direction</code>     | character string, partially matched to either <code>"wide"</code> to reshape to wide format, or <code>"long"</code> to reshape to long format.                                                                                                                                                                                                                                                                                  |
| <code>new.row.names</code> | character or NULL: a non-null value will be used for the row names of the result.                                                                                                                                                                                                                                                                                                                                               |
| <code>sep</code>           | A character vector of length 1, indicating a separating character in the variable names in the wide format. This is used for guessing <code>v.names</code> and <code>times</code> arguments based on the names in <code>varying</code> . If <code>sep == ""</code> , the split is just before the first numeral that follows an alphabetic character. This is also used to create variable names when reshaping to wide format. |
| <code>split</code>         | A list with three components, <code>regex</code> , <code>include</code> , and (optionally) <code>fixed</code> . This allows an extended interface to variable name splitting. See ‘Details’.                                                                                                                                                                                                                                    |

## Details

Although `reshape()` can be used in a variety of contexts, the motivating application is data from longitudinal studies, and the arguments of this function are named and described in those terms. A longitudinal study is characterized by repeated measurements of the same variable(s), e.g., height and weight, on each unit being studied (e.g., individual persons) at different time points (which are assumed to be the same for all units). These variables are called time-varying variables. The study may include other variables that are measured only once for each unit and do not vary with time (e.g., gender and race); these are called time-constant variables.

A ‘wide’ format representation of a longitudinal dataset will have one record (row) for each unit, typically with some time-constant variables that occupy single columns, and some time-varying variables that occupy multiple columns (one column for each time point). A ‘long’ format representation of the same dataset will have multiple records (rows) for each individual, with the time-constant variables being constant across these records and the time-varying variables varying across the records. The ‘long’ format dataset will have two additional variables: a ‘time’ variable identifying which time point each record comes from, and an ‘id’ variable showing which records refer to the same unit.

The type of conversion (long to wide or wide to long) is determined by the `direction` argument, which is mandatory unless the data argument is the result of a previous call to `reshape`. In that case, the operation can be reversed simply using `reshape(data)` (the other arguments are stored as attributes on the data frame).

Conversion from long to wide format with `direction = "wide"` is the simpler operation, and is mainly useful in the context of multivariate analysis where data is often expected as a wide-format

matrix. In this case, the time variable `timevar` and id variable `idvar` must be specified. All other variables are assumed to be time-varying, unless the time-varying variables are explicitly specified via the `v.names` argument. A warning is issued if time-constant variables are not actually constant.

Each time-varying variable is expanded into multiple variables in the wide format. The names of these expanded variables are generated automatically, unless they are specified as the `varying` argument in the form of a list (or matrix) with one component (or row) for each time-varying variable. If `varying` is a vector of names, it is implicitly converted into a matrix, with one row for each time-varying variable. Use this option with care if there are multiple time-varying variables, as the ordering (by column, the default in the `matrix` constructor) may be unintuitive, whereas the explicit list or matrix form is unambiguous.

Conversion from wide to long with `direction = "long"` is the more common operation as most (univariate) statistical modeling functions expect data in the long format. In the simpler case where there is only one time-varying variable, the corresponding columns in the wide format input can be specified as the `varying` argument, which can be either a vector of column names or the corresponding column indices. The name of the corresponding variable in the long format output combining these columns can be optionally specified as the `v.names` argument, and the name of the time variables as the `timevar` argument. The values to use as the time values corresponding to the different columns in the wide format can be specified as the `times` argument. If `v.names` is unspecified, the function will attempt to guess `v.names` and `times` from `varying` (an explicitly specified `times` argument is unused in that case). The default expects variable names like `x.1`, `x.2`, where `sep = "."` specifies to split at the dot and drop it from the name. To have alphabetic followed by numeric times use `sep = ""`.

Multiple time-varying variables can be specified in two ways, either with `varying` as an atomic vector as above, or as a list (or a matrix). The first form is useful (and mandatory) if the automatic variable name splitting as described above is used; this requires the names of all time-varying variables to be suitably formatted in the same manner, and `v.names` to be unspecified. If `varying` is a list (with one component for each time-varying variable) or a matrix (one row for each time-varying variable), variable name splitting is not attempted, and `v.names` and `times` will generally need to be specified, although they will default to, respectively, the first variable name in each set, and sequential times.

Also, guessing is not attempted if `v.names` is given explicitly, even if `varying` is an atomic vector. In that case, the number of time-varying variables is taken to be the length of `v.names`, and `varying` is implicitly converted into a matrix, with one row for each time-varying variable. As in the case of long to wide conversion, the matrix is filled up by column, so careful attention needs to be paid to the order of variable names (or indices) in `varying`, which is taken to be like `x.1`, `y.1`, `x.2`, `y.2` (i.e., variables corresponding to the same time point need to be grouped together).

The `split` argument should not usually be necessary. The `split$regexp` component is passed to either `strsplit` or `regexpr`, where the latter is used if `split$include` is `TRUE`, in which case the splitting occurs after the first character of the matched string. In the `strsplit` case, the separator is not included in the result, and it is possible to specify fixed-string matching using `split$fixed`.

## Value

The reshaped data frame with added attributes to simplify reshaping back to the original form.

## See Also

`stack`, `aperm`; `relist` for reshaping the result of `unlist`. `xtabs` and `as.data.frame.table` for creating contingency tables and converting them back to data frames.

`vignette("reshape")` for detailed examples.

**Examples**

```

summary(Indometh) # data in long format

## long to wide (direction = "wide") requires idvar and timevar at a minimum
reshape(Indometh, direction = "wide", idvar = "Subject", timevar = "time")

## can also explicitly specify name of combined variable
wide <- reshape(Indometh, direction = "wide", idvar = "Subject",
               timevar = "time", v.names = "conc", sep = "_")
wide

## reverse transformation
reshape(wide, direction = "long")
reshape(wide, idvar = "Subject", varying = list(2:12),
       v.names = "conc", direction = "long")

## times need not be numeric
df <- data.frame(id = rep(1:4, rep(2,4)),
               visit = rep(c("Before", "After"), 4),
               x = rnorm(4), y = runif(4))
df
reshape(df, timevar = "visit", idvar = "id", direction = "wide")
## warns that y is really varying
reshape(df, timevar = "visit", idvar = "id", direction = "wide", v.names = "x")

## unbalanced 'long' data leads to NA fill in 'wide' form
df2 <- df[1:7, ]
df2
reshape(df2, timevar = "visit", idvar = "id", direction = "wide")

## Alternative regular expressions for guessing names
df3 <- data.frame(id = 1:4, age = c(40,50,60,50), dose1 = c(1,2,1,2),
               dose2 = c(2,1,2,1), dose4 = c(3,3,3,3))
reshape(df3, direction = "long", varying = 3:5, sep = "")

## an example that isn't longitudinal data
state.x77 <- as.data.frame(state.x77)
long <- reshape(state.x77, idvar = "state", ids = row.names(state.x77),
               times = names(state.x77), timevar = "Characteristic",
               varying = list(names(state.x77)), direction = "long")

reshape(long, direction = "wide")

reshape(long, direction = "wide", new.row.names = unique(long$state))

## multiple id variables
df3 <- data.frame(school = rep(1:3, each = 4), class = rep(9:10, 6),
               time = rep(c(1,1,2,2), 3), score = rnorm(12))
wide <- reshape(df3, idvar = c("school", "class"), direction = "wide")
wide
## transform back
reshape(wide)

```

residuals

*Extract Model Residuals***Description**

`residuals` is a generic function which extracts model residuals from objects returned by modeling functions.

`resid` is an alias for `residuals`, abbreviated to encourage users to access object components through an accessor function rather than by directly referencing an object slot.

All object classes which are returned by model fitting functions should provide a `residuals` method. (Note that the method is for ‘`residuals`’ and not ‘`resid`’.)

Methods can make use of `naresid` methods to compensate for the omission of missing values. The default, `nls` and `smooth.spline` methods do.

**Usage**

```
residuals(object, ...)
resid(object, ...)
```

**Arguments**

|                     |                                                                      |
|---------------------|----------------------------------------------------------------------|
| <code>object</code> | an object for which the extraction of model residuals is meaningful. |
| <code>...</code>    | other arguments.                                                     |

**Value**

Residuals extracted from the object `object`.

Chambers, J. M. and Hastie, T. J. (1992) *Statistical Models in S*. Wadsworth & Brooks/Cole.

**See Also**

`coefficients`, `fitted.values`, `glm`, `lm`.

`influence.measures` for standardized (`rstandard`) and studentized (`rstudent`) residuals.

runmed

*Running Medians – Robust Scatter Plot Smoothing***Description**

Compute running medians of odd span. This is the ‘most robust’ scatter plot smoothing possible. For efficiency (and historical reason), you can use one of two different algorithms giving identical results.

## Usage

```
runmed(x, k, endrule = c("median", "keep", "constant"),
      algorithm = NULL,
      na.action = c("+Big_alternate", "-Big_alternate", "na.omit", "fail"),
      print.level = 0)
```

## Arguments

|             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|-------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| x           | numeric vector, the ‘dependent’ variable to be smoothed.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| k           | integer width of median window; must be odd. Turlach had a default of $k \leftarrow 1 + 2 * \min((n-1) \% 2, \text{ceiling}(0.1 * n))$ . Use $k = 3$ for ‘minimal’ robust smoothing eliminating isolated outliers.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| endrule     | character string indicating how the values at the beginning and the end (of the data) should be treated. Can be abbreviated. Possible values are:<br>“keep” keeps the first and last $k_2$ values at both ends, where $k_2$ is the half-bandwidth $k_2 = k \% 2$ , i.e., $y[j] = x[j]$ for $j \in \{1, \dots, k_2; n - k_2 + 1, \dots, n\}$ ;<br>“constant” copies <code>median(y[1:k2])</code> to the first values and analogously for the last ones making the smoothed ends <i>constant</i> ;<br>“median” the default, smooths the ends by using symmetrical medians of subsequently smaller bandwidth, but for the very first and last value where Tukey’s robust end-point rule is applied, see <a href="#">smoothEnds</a> . |
| algorithm   | character string (partially matching “Turlach” or “Stuetzle”) or the default NULL, specifying which algorithm should be applied. The default choice depends on $n = \text{length}(x)$ and $k$ where “Turlach” will be used for larger problems.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| na.action   | character string determining the behavior in the case of NA or NaN in x, (partially matching) one of<br>“+Big_alternate” Here, all the NAs in x are first replaced by alternating $\pm B$ where $B$ is a “Big” number (with $2B < M^*$ , where $M^* = .Machine\$double.xmax$ ). The replacement values are “from left” $(+B, -B, +B, \dots)$ , i.e. start with “+”.<br>“-Big_alternate” almost the same as “+Big_alternate”, just starting with $-B$ (“-Big...”).<br>“na.omit” the result is the same as <code>runmed(x[!is.na(x)], k, ...)</code> .<br>“fail” the presence of NAs in x will raise an error.                                                                                                                      |
| print.level | integer, indicating verbosity of algorithm; should rarely be changed by average users.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

## Details

Apart from the end values, the result  $y = \text{runmed}(x, k)$  simply has  $y[j] = \text{median}(x[(j-k_2):(j+k_2)])$  ( $k = 2*k_2+1$ ), computed very efficiently.

The two algorithms are internally entirely different:

“Turlach” is the Härdle–Steiger algorithm (see Ref.) as implemented by Berwin Turlach. A tree algorithm is used, ensuring performance  $O(n \log k)$  where  $n = \text{length}(x)$  which is asymptotically optimal.

“Stuetzle” is the (older) Stuetzle–Friedman implementation which makes use of median *updating* when one observation enters and one leaves the smoothing window. While this performs as  $O(n \times k)$  which is slower asymptotically, it is considerably faster for small  $k$  or  $n$ .

Note that, both algorithms (and the `smoothEnds()` utility) now “work” also when `x` contains non-finite entries ( $\pm\text{Inf}$ , `NaN`, and `NA`):

"Turlach" .....

"Stuetzle" currently simply works by applying the underlying math library ('libm') arithmetic for the non-finite numbers; this may optionally change in the future.

Currently [long vectors](#) are only supported for `algorithm = "Stuetzle"`.

## Value

vector of smoothed values of the same length as `x` with an `attribute` `k` containing (the ‘oddified’) `k`.

## Author(s)

Martin Maechler <maechler@stat.math.ethz.ch>, based on Fortran code from Werner Stuetzle and S-PLUS and C code from Berwin Turlach.

## References

Jerome H. Friedman and Werner Stuetzle (1982) *Smoothing of Scatterplots*; Report, Dep. Statistics, Stanford U., Project Orion 003.

## See Also

`smoothEnds` which implements Tukey’s end point rule and is called by default from `runmed(*, endrule = "median")`. `smooth` uses running medians of 3 for its compound smoothers.

## Examples

```
require(graphics)

utils::example(nhtemp)
myNHT <- as.vector(nhtemp)
myNHT[20] <- 2 * nhtemp[20]
plot(myNHT, type = "b", ylim = c(48, 60), main = "Running Medians Example")
lines(runmed(myNHT, 7), col = "red")

## special: multiple y values for one x
plot(cars, main = "'cars' data and runmed(dist, 3)")
lines(cars, col = "light gray", type = "c")
with(cars, lines(speed, runmed(dist, k = 3), col = "red"))

## nice quadratic with a few outliers
y <- ys <- (-20:20)^2
y[c(1,10,21,41)] <- c(150, 30, 400, 450)
all(y == runmed(y, 1)) # 1-neighbourhood <==> interpolation
plot(y) ## lines(y, lwd = .1, col = "light gray")
lines(lowess(seq(y), y, f = 0.3), col = "brown")
lines(runmed(y, 7), lwd = 2, col = "blue")
lines(runmed(y, 11), lwd = 2, col = "red")

## Lowess is not robust
```

```

y <- ys ; y[21] <- 6666 ; x <- seq(y)
col <- c("black", "brown", "blue")
plot(y, col = col[1])
lines(lowess(x, y, f = 0.3), col = col[2])
lines(runmed(y, 7), lwd = 2, col = col[3])
legend(length(y), max(y), c("data", "lowess(y, f = 0.3)", "runmed(y, 7)"),
      xjust = 1, col = col, lty = c(0, 1, 1), pch = c(1, NA, NA))

## An example with initial NA's - used to fail badly (notably for "Turlach"):
x15 <- c(rep(NA, 4), c(9, 9, 4, 22, 6, 1, 7, 5, 2, 8, 3))
rS15 <- cbind(Sk.3 = runmed(x15, k = 3, algorithm="S"),
             Sk.7 = runmed(x15, k = 7, algorithm="S"),
             Sk.11 = runmed(x15, k = 11, algorithm="S"))
rT15 <- cbind(Tk.3 = runmed(x15, k = 3, algorithm="T", print.level=1),
             Tk.7 = runmed(x15, k = 7, algorithm="T", print.level=1),
             Tk.9 = runmed(x15, k = 9, algorithm="T", print.level=1),
             Tk.11 = runmed(x15, k = 11, algorithm="T", print.level=1))
cbind(x15, rS15, rT15) # result for k=11 maybe a bit surprising ..
Tv <- rT15[1:3,]
stopifnot(3 <= Tv, Tv <= 9, 5 <= Tv[1:10,])
matplot(y = cbind(x15, rT15), type = "b", ylim = c(1, 9), pch=1:5, xlab = NA,
      main = "runmed(x15, k, algo = \"Turlach\")")
mtext(paste("x15 <- ", deparse(x15)))
points(x15, cex=2)
legend("bottomleft", legend=c("data", paste("k = ", c(3, 7, 9, 11))),
      bty="n", col=1:5, lty=1:5, pch=1:5)

```

rWishart

*Random Wishart Distributed Matrices***Description**

Generate  $n$  random matrices, distributed according to the Wishart distribution with parameters  $\Sigma$  and  $df$ ,  $W_p(\Sigma, m)$ ,  $m = df$ ,  $\Sigma = \text{Sigma}$ .

**Usage**

```
rWishart(n, df, Sigma)
```

**Arguments**

|                |                                                                                              |
|----------------|----------------------------------------------------------------------------------------------|
| $n$            | integer sample size.                                                                         |
| $df$           | numeric parameter, “degrees of freedom”.                                                     |
| $\text{Sigma}$ | positive definite ( $p \times p$ ) “scale” matrix, the matrix parameter of the distribution. |

**Details**

If  $X_1, \dots, X_m$ ,  $X_i \in \mathbf{R}^p$  is a sample of  $m$  independent multivariate Gaussians with mean (vector) 0, and covariance matrix  $\Sigma$ , the distribution of  $M = X'X$  is  $W_p(\Sigma, m)$ .

Consequently, the expectation of  $M$  is

$$E[M] = m \times \Sigma.$$

Further, if Sigma is scalar ( $p = 1$ ), the Wishart distribution is a scaled chi-squared ( $\chi^2$ ) distribution with df degrees of freedom,  $W_1(\sigma^2, m) = \sigma^2 \chi_m^2$ .

The component wise variance is

$$\text{Var}(M_{ij}) = m(\Sigma_{ij}^2 + \Sigma_{ii}\Sigma_{jj}).$$

### Value

a numeric [array](#), say R, of dimension  $p \times p \times n$ , where each  $R[, , i]$  is a positive definite matrix, a realization of the Wishart distribution  $W_p(\Sigma, m)$ ,  $m = \text{df}$ ,  $\Sigma = \text{Sigma}$ .

### Examples

```
## Artificial
S <- toeplitz((10:1)/10)
set.seed(11)
R <- rWishart(1000, 20, S)
dim(R) # 10 10 1000
mR <- apply(R, 1:2, mean) # ~ E[ Wish(S, 20) ] = 20 * S
stopifnot(all.equal(mR, 20*S, tolerance = .009))

## See Details, the variance is
Va <- 20*(S^2 + tcrossprod(diag(S)))
vR <- apply(R, 1:2, var)
stopifnot(all.equal(vR, Va, tolerance = 1/16))
```

---

scatter.smooth

---

Scatter Plot with Smooth Curve Fitted by loess

---

### Description

Plot and add a smooth curve computed by loess to a scatter plot.

### Usage

```
scatter.smooth(x, y = NULL, span = 2/3, degree = 1,
  family = c("symmetric", "gaussian"),
  xlab = NULL, ylab = NULL,
  ylim = range(y, pred$y, na.rm = TRUE),
  evaluation = 50, ..., lpars = list())

loess.smooth(x, y, span = 2/3, degree = 1,
  family = c("symmetric", "gaussian"), evaluation = 50, ...)
```

## Arguments

|                         |                                                                                                                                                                                                                                               |
|-------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x, y</code>       | the <code>x</code> and <code>y</code> arguments provide the <code>x</code> and <code>y</code> coordinates for the plot. Any reasonable way of defining the coordinates is acceptable. See the function <a href="#">xy.coords</a> for details. |
| <code>span</code>       | smoothness parameter for loess.                                                                                                                                                                                                               |
| <code>degree</code>     | degree of local polynomial used.                                                                                                                                                                                                              |
| <code>family</code>     | if "gaussian" fitting is by least-squares, and if <code>family = "symmetric"</code> a re-descending M estimator is used. Can be abbreviated.                                                                                                  |
| <code>xlab</code>       | label for <code>x</code> axis.                                                                                                                                                                                                                |
| <code>ylab</code>       | label for <code>y</code> axis.                                                                                                                                                                                                                |
| <code>ylim</code>       | the <code>y</code> limits of the plot.                                                                                                                                                                                                        |
| <code>evaluation</code> | number of points at which to evaluate the smooth curve.                                                                                                                                                                                       |
| <code>...</code>        | For <code>scatter.smooth()</code> , graphical parameters, passed to <code>plot()</code> only. For <code>loess.smooth</code> , control parameters passed to <a href="#">loess.control</a> .                                                    |
| <code>lpars</code>      | a <a href="#">list</a> of arguments to be passed to <a href="#">lines()</a> .                                                                                                                                                                 |

## Details

`loess.smooth` is an auxiliary function which evaluates the loess smooth at `evaluation` equally spaced points covering the range of `x`.

## Value

For `scatter.smooth`, none.

For `loess.smooth`, a list with two components, `x` (the grid of evaluation points) and `y` (the smoothed values at the grid points).

## See Also

[loess](#); [smoothScatter](#) for scatter plots with smoothed *density* color representation.

## Examples

```
require(graphics)

with(cars, scatter.smooth(speed, dist))
## or with dotted thick smoothed line results :
with(cars, scatter.smooth(speed, dist, lpars =
  list(col = "red", lwd = 3, lty = 3)))
```

---

screeplot

*Scree Plots*

---

## Description

`screeplot.default` plots the variances against the number of the principal component. This is also the plot method for classes `"princomp"` and `"prcomp"`.

## Usage

```
screeplot(x, ...)
## Default S3 method:
screeplot(x, npcs = min(10, length(x$sdev)),
          type = c("barplot", "lines"),
          main = deparse1(substitute(x)), ...)
```

## Arguments

|                        |                                                                                                                                  |
|------------------------|----------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>         | an object containing a <code>sdev</code> component, such as that returned by <code>princomp()</code> and <code>prcomp()</code> . |
| <code>npcs</code>      | the number of components to be plotted.                                                                                          |
| <code>type</code>      | the type of plot. Can be abbreviated.                                                                                            |
| <code>main, ...</code> | graphics parameters.                                                                                                             |

## See Also

[princomp](#) and [prcomp](#).

## Examples

```
require(graphics)

## The variances of the variables in the
## USArrests data vary by orders of magnitude, so scaling is appropriate
(pc.cr <- princomp(USArrests, cor = TRUE)) # inappropriate
screeplot(pc.cr)

fit <- princomp(covmat = Harman74.cor)
screeplot(fit)
screeplot(fit, npcs = 24, type = "lines")
```

---

|    |                           |
|----|---------------------------|
| sd | <i>Standard Deviation</i> |
|----|---------------------------|

---

### Description

This function computes the standard deviation of the values in `x`. If `na.rm` is TRUE then missing values are removed before computation proceeds.

### Usage

```
sd(x, na.rm = FALSE)
```

### Arguments

|                    |                                                                                                                      |
|--------------------|----------------------------------------------------------------------------------------------------------------------|
| <code>x</code>     | a numeric vector or an R object but not a <a href="#">factor</a> coercible to numeric by <code>as.double(x)</code> . |
| <code>na.rm</code> | logical. Should missing values be removed?                                                                           |

### Details

Like [var](#) this uses denominator  $n - 1$ .

The standard deviation of a length-one or zero-length vector is NA.

### See Also

[var](#) for its square, and [mad](#), the most robust alternative.

### Examples

```
sd(1:2) ^ 2
```

---

|             |                                                     |
|-------------|-----------------------------------------------------|
| se.contrast | <i>Standard Errors for Contrasts in Model Terms</i> |
|-------------|-----------------------------------------------------|

---

### Description

Returns the standard errors for one or more contrasts in an aov object.

### Usage

```
se.contrast(object, ...)
## S3 method for class 'aov'
se.contrast(object, contrast.obj,
             coef = contr.helmert(ncol(contrast))[, 1],
             data = NULL, ...)
```

## Arguments

|                           |                                                                                                                                                                                                                                                                                                                                        |
|---------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>object</code>       | A suitable fit, usually from <code>aov</code> .                                                                                                                                                                                                                                                                                        |
| <code>contrast.obj</code> | The contrasts for which standard errors are requested. This can be specified via a list or via a matrix. A single contrast can be specified by a list of logical vectors giving the cells to be contrasted. Multiple contrasts should be specified by a matrix, each column of which is a numerical contrast vector (summing to zero). |
| <code>coef</code>         | used when <code>contrast.obj</code> is a list; it should be a vector of the same length as the list with zero sum. The default value is the first Helmert contrast, which contrasts the first and second cell means specified by the list.                                                                                             |
| <code>data</code>         | The data frame used to evaluate <code>contrast.obj</code> .                                                                                                                                                                                                                                                                            |
| <code>...</code>          | further arguments passed to or from other methods.                                                                                                                                                                                                                                                                                     |

## Details

Contrasts are usually used to test if certain means are significantly different; it can be easier to use `se.contrast` than compute them directly from the coefficients.

In multistratum models, the contrasts can appear in more than one stratum, in which case the standard errors are computed in the lowest stratum and adjusted for efficiencies and comparisons between strata. (See the comments in the note in the help for `aov` about using orthogonal contrasts.) Such standard errors are often conservative.

Suitable matrices for use with `coef` can be found by calling `contrasts` and indexing the columns by a factor.

## Value

A vector giving the standard errors for each contrast.

## See Also

[contrasts](#), [model.tables](#)

```

## Description

Construct self-starting nonlinear models to be used in [nls](#), etc. Via function `initial` to compute approximate parameter values from data, such models are “self-starting”, i.e., do not need a `start` argument in, e.g., [nls\(\)](#).

## Usage

```
selfStart(model, initial, parameters, template)
```

## Arguments

|                         |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|-------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>model</code>      | a function object defining a nonlinear model or a nonlinear <a href="#">formula</a> object of the form <code>~ expression</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <code>initial</code>    | a function object, taking arguments <code>mCall</code> , <code>data</code> , and <code>LHS</code> , <i>and</i> <code>...</code> , representing, respectively, a matched call to the function <code>model</code> , a data frame in which to interpret the variables in <code>mCall</code> , and the expression from the left-hand side of the model formula in the call to <code>nls</code> . This function should return initial values for the parameters in <code>model</code> . The <code>...</code> is used by <a href="#">nls()</a> to pass its control and trace arguments for the cases where <code>initial()</code> itself calls <code>nls()</code> as it does for the ten self-starting nonlinear models in R’s <b>stats</b> package. |
| <code>parameters</code> | a character vector specifying the terms on the right hand side of <code>model</code> for which initial estimates should be calculated. Passed as the <code>namevec</code> argument to the <code>deriv</code> function.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <code>template</code>   | an optional prototype for the calling sequence of the returned object, passed as the <code>function.arg</code> argument to the <code>deriv</code> function. By default, a template is generated with the covariates in <code>model</code> coming first and the parameters in <code>model</code> coming last in the calling sequence.                                                                                                                                                                                                                                                                                                                                                                                                           |

## Details

[nls\(\)](#) calls [getInitial](#) and the `initial` function for these self-starting models.

This function is generic; methods functions can be written to handle specific classes of objects.

## Value

a [function](#) object of class “selfStart”, for the formula method obtained by applying [deriv](#) to the right hand side of the model formula. An `initial` attribute (defined by the `initial` argument) is added to the function to calculate starting estimates for the parameters in the model automatically.

## Author(s)

José Pinheiro and Douglas Bates

## See Also

[nls](#), [getInitial](#).

Each of the following are “selfStart” models (with examples) [SSasympt](#), [SSasymptOff](#), [SSasymptOrig](#), [SSbiexp](#), [SSfol](#), [SSfpl](#), [SSgomptertz](#), [SSlogis](#), [SSmicmen](#), [SSweibull](#).

Further, package **nlme**’s [nlsList](#).

**Examples**

```
## self-starting logistic model

## The "initializer" (finds initial values for parameters from data):
initLogis <- function(mCall, data, LHS, ...) {
  xy <- sortedXyData(mCall[["x"]], LHS, data)
  if(nrow(xy) < 4)
    stop("too few distinct input values to fit a logistic model")
  z <- xy[["y"]]
  ## transform to proportion, i.e. in (0,1) :
  rng <- range(z); dz <- diff(rng)
  z <- (z - rng[1L] + 0.05 * dz)/(1.1 * dz)
  xy[["z"]] <- log(z/(1 - z)) # logit transformation
  aux <- coef(lm(x ~ z, xy))
  pars <- coef(nls(y ~ 1/(1 + exp((xmid - x)/scal)),
    data = xy,
    start = list(xmid = aux[[1L]], scal = aux[[2L]]),
    algorithm = "plinear", ...)
  setNames(pars [c(".lin", "xmid", "scal")],
    mCall[c("Asym", "xmid", "scal")])
}

mySSlogis <- selfStart(~ Asym/(1 + exp((xmid - x)/scal)),
  initial = initLogis,
  parameters = c("Asym", "xmid", "scal"))

getInitial(weight ~ mySSlogis(Time, Asym, xmid, scal),
  data = subset(ChickWeight, Chick == 1))

# 'first.order.log.model' is a function object defining a first order
# compartment model
# 'first.order.log.initial' is a function object which calculates initial
# values for the parameters in 'first.order.log.model'
#
# self-starting first order compartment model
## Not run:
SSfol <- selfStart(first.order.log.model, first.order.log.initial)

## End(Not run)

## Explore the self-starting models already available in R's "stats":
pos.st <- which("package:stats" == search())
mSS <- apropos("^SS..", where = TRUE, ignore.case = FALSE)
(mSS <- unname(mSS[names(mSS) == pos.st]))
fSS <- sapply(mSS, get, pos = pos.st, mode = "function")
all(sapply(fSS, inherits, "selfStart")) # -> TRUE

## Show the argument list of each self-starting function:
str(fSS, give.attr = FALSE)
```

**Description**

This is a convenience function that sets the names on an object and returns the object. It is most useful at the end of a function definition where one is creating the object to be returned and would prefer not to store it under a name just so the names can be assigned.

**Usage**

```
setNames(object = nm, nm)
```

**Arguments**

|        |                                                          |
|--------|----------------------------------------------------------|
| object | an object for which a names attribute will be meaningful |
| nm     | a character vector of names to assign to the object      |

**Value**

An object of the same sort as object with the new names assigned.

**Author(s)**

Douglas M. Bates and Saikat DebRoy

**See Also**

[unname](#) for removing names.

**Examples**

```
setNames( 1:3, c("foo", "bar", "baz") )  
# this is just a short form of  
tmp <- 1:3  
names(tmp) <- c("foo", "bar", "baz")  
tmp  
  
## special case of character vector, using default  
setNames(nm = c("First", "2nd"))
```

---

shapiro.test

*Shapiro-Wilk Normality Test*

---

**Description**

Performs the Shapiro-Wilk test of normality.

**Usage**

```
shapiro.test(x)
```

**Arguments**

|   |                                                                                                                               |
|---|-------------------------------------------------------------------------------------------------------------------------------|
| x | a numeric vector of data values. Missing values are allowed, but the number of non-missing values must be between 3 and 5000. |
|---|-------------------------------------------------------------------------------------------------------------------------------|

## Value

A list with class "htest" containing the following components:

|           |                                                                                                          |
|-----------|----------------------------------------------------------------------------------------------------------|
| statistic | the value of the Shapiro-Wilk statistic.                                                                 |
| p.value   | an approximate p-value for the test. This is said in Royston (1995) to be adequate for $p.value < 0.1$ . |
| method    | the character string "Shapiro-Wilk normality test".                                                      |
| data.name | a character string giving the name(s) of the data.                                                       |

## Source

The algorithm used is a C translation of the Fortran code described in Royston (1995). The calculation of the p value is exact for  $n = 3$ , otherwise approximations are used, separately for  $4 \leq n \leq 11$  and  $n \geq 12$ .

```

---

sigma

*Extract Residual Standard Deviation 'Sigma'*

---

## Description

Extract the estimated standard deviation of the errors, the “residual standard deviation” (misnamed also “residual standard error”, e.g., in [summary.lm\(\)](#)'s output, from a fitted model).

Many classical statistical models have a *scale parameter*, typically the standard deviation of a zero-mean normal (or Gaussian) random variable which is denoted as  $\sigma$ . `sigma(.)` extracts the *estimated* parameter from a fitted model, i.e.,  $\hat{\sigma}$ .

## Usage

```
sigma(object, ...)

## Default S3 method:
sigma(object, use.fallback = TRUE, ...)
```

## Arguments

**object** an R object, typically resulting from a model fitting function such as `lm`.  
**use.fallback** logical, passed to `nobs`.  
**...** potentially further arguments passed to and from methods. Passed to `deviance(*, ...)` for the default method.

## Details

The **stats** package provides the S3 generic, a default method, and a method for objects of class "glm". The default method is correct typically for (asymptotically / approximately) generalized gaussian ("least squares") problems, since it is defined as

```
sigma.default <- function (object, use.fallback = TRUE, ...)
  sqrt( deviance(object, ...) / (NN - PP) )
```

where `NN <- nobs(object, use.fallback = use.fallback)` and `PP <- sum(!is.na(coef(object)))` – where in older R versions this was `length(coef(object))` which is too large in case of undetermined coefficients, e.g., for rank deficient model fits.

## Value

Typically a number, the estimated standard deviation of the errors ("residual standard deviation") for Gaussian models, and—less interpretably—the square root of the residual deviance per degree of freedom in more general models.

Very strictly speaking,  $\hat{\sigma}$  ("σ hat") is actually  $\sqrt{\hat{\sigma}^2}$ .

For generalized linear models (class "glm"), the `sigma.glm` method returns the square root of the dispersion parameter (See `summary.glm`). For families with free dispersion parameter, *sigma* is estimated from the root mean square of the Pearson residuals. For families with fixed dispersion, *sigma* is not estimated from the residuals but extracted directly from the family of the fitted model. Consequently, for binomial or Poisson GLMs, *sigma* is exactly 1.

For multivariate linear models (class "mlm"), a *vector* of sigmas is returned, each corresponding to one column of *Y*.

## Note

The misnomer "Residual standard **error**" has been part of too many R (and S) outputs to be easily changed there.

## See Also

`deviance`, `nobs`, `vcov`, `summary.glm`.

## Examples

```
## -- lm() -----
lm1 <- lm(Fertility ~ ., data = swiss)
sigma(lm1) # ~ 7.165 = "Residual standard error" printed from summary(lm1)
stopifnot(all.equal(sigma(lm1), summary(lm1)$sigma, tolerance=1e-15))

## -- nls() -----
DNase1 <- subset(DNase, Run == 1)
```

```

fm.DN1 <- nls(density ~ SSlogis(log(conc), Asym, xmid, scal), DNase1)
sigma(fm.DN1) # ~= 0.01919 as from summary(..)
stopifnot(all.equal(sigma(fm.DN1), summary(fm.DN1)$sigma, tolerance=1e-15))

sigma(mlmfit) # is the same as {but more efficient than}
sqrt(diag(estVar(mlmfit)))

```

SignRank

*Distribution of the Wilcoxon Signed Rank Statistic***Description**

Density, distribution function, quantile function and random generation for the distribution of the Wilcoxon Signed Rank statistic obtained from a sample with size  $n$ .

**Usage**

```

dsignrank(x, n, log = FALSE)
psignrank(q, n, lower.tail = TRUE, log.p = FALSE)
qsignrank(p, n, lower.tail = TRUE, log.p = FALSE)
rsignrank(nn, n)

```

**Arguments**

|        |                                                                                                     |
|--------|-----------------------------------------------------------------------------------------------------|
| $x, q$ | vector of quantiles.                                                                                |
| $p$    | vector of probabilities.                                                                            |
| $nn$   | number of observations. If $\text{length}(nn) > 1$ , the length is taken to be the number required. |

|                         |                                                                                               |
|-------------------------|-----------------------------------------------------------------------------------------------|
| <code>n</code>          | number(s) of observations in the sample(s). A positive integer, or a vector of such integers. |
| <code>log, log.p</code> | logical; if TRUE, probabilities <code>p</code> are given as $\log(p)$ .                       |
| <code>lower.tail</code> | logical; if TRUE (default), probabilities are $P[X \leq x]$ , otherwise, $P[X > x]$ .         |

### Details

This distribution is obtained as follows. Let  $x$  be a sample of size  $n$  from a continuous distribution symmetric about the origin. Then the Wilcoxon signed rank statistic is the sum of the ranks of the absolute values  $x[i]$  for which  $x[i]$  is positive. This statistic takes values between 0 and  $n(n+1)/2$ , and its mean and variance are  $n(n+1)/4$  and  $n(n+1)(2n+1)/24$ , respectively.

If either of the first two arguments is a vector, the recycling rule is used to do the calculations for all combinations of the two up to the length of the longer vector.

### Value

`dsignrank` gives the density, `psignrank` gives the distribution function, `qsignrank` gives the quantile function, and `rsignrank` generates random deviates.

The length of the result is determined by `nn` for `rsignrank`, and is the maximum of the lengths of the numerical arguments for the other functions.

The numerical arguments other than `nn` are recycled to the length of the result. Only the first elements of the logical arguments are used.

### Examples

```
require(graphics)

par(mfrow = c(2,2))
for(n in c(4:5,10,40)) {
  x <- seq(0, n*(n+1)/2, length.out = 501)
  plot(x, dsignrank(x, n = n), type = "l",
       main = paste0("dsignrank(x, n = ", n, ")"))
}
```

simulate

*Simulate Responses***Description**

Simulate one or more responses from the distribution corresponding to a fitted model object.

**Usage**

```
simulate(object, nsim = 1, seed = NULL, ...)
```

**Arguments**

|                     |                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|---------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>object</code> | an object representing a fitted model.                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <code>nsim</code>   | number of response vectors to simulate. Defaults to 1.                                                                                                                                                                                                                                                                                                                                                                                                          |
| <code>seed</code>   | an object specifying if and how the random number generator should be initialized ('seeded').<br>For the "lm" method, either NULL or an integer that will be used in a call to <code>set.seed</code> before simulating the response vectors. If set, the value is saved as the "seed" attribute of the returned value. The default, NULL will not change the random generator state, and return <code>.Random.seed</code> as the "seed" attribute, see 'Value'. |
| <code>...</code>    | additional optional arguments.                                                                                                                                                                                                                                                                                                                                                                                                                                  |

**Details**

This is a generic function. Consult the individual modeling functions for details on how to use this function.

Package **stats** has a method for "lm" objects which is used for `lm` and `glm` fits. There is a method for fits from `glm.nb` in package **MASS**, and hence the case of negative binomial families is not covered by the "lm" method.

The methods for linear models fitted by `lm` or `glm(family = "gaussian")` assume that any weights which have been supplied are inversely proportional to the error variance. For other GLMs the (optional) `simulate` component of the `family` object is used—there is no appropriate simulation method for 'quasi' models as they are specified only up to two moments.

For binomial and Poisson GLMs the dispersion is fixed at one. Integer prior weights  $w_i$  can be interpreted as meaning that observation  $i$  is an average of  $w_i$  observations, which is natural for binomials specified as proportions but less so for a Poisson, for which prior weights are ignored with a warning.

For a gamma GLM the shape parameter is estimated by maximum likelihood (using function `gamma.shape` in package **MASS**). The interpretation of weights is as multipliers to a basic shape parameter, since dispersion is inversely proportional to shape.

For an inverse gaussian GLM the model assumed is  $IG(\mu_i, \lambda w_i)$  (see [https://en.wikipedia.org/wiki/Inverse\\_Gaussian\\_distribution](https://en.wikipedia.org/wiki/Inverse_Gaussian_distribution)) where  $\lambda$  is estimated by the inverse of the dispersion estimate for the fit. The variance is  $\mu_i^3/(\lambda w_i)$  and hence inversely proportional to the prior weights. The simulation is done by function `rinvGauss` from the **SuppDists** package, which must be installed.

## Value

Typically, a list of length `nsim` of simulated responses. Where appropriate the result can be a data frame (which is a special type of list).

For the "lm" method, the result is a data frame with an attribute "seed". If argument `seed` is `NULL`, the attribute is the value of `.Random.seed` before the simulation was started; otherwise it is the value of the argument with a "kind" attribute with value as `.list(RNGkind())`.

## See Also

[RNG](#) about random number generation in R, [fitted.values](#) and [residuals](#) for related methods; [glm](#), [lm](#) for model fitting.

There are further examples in the 'simulate.R' tests file in the sources for package **stats**.

## Examples

```
x <- 1:5
mod1 <- lm(c(1:3, 7, 6) ~ x)
S1 <- simulate(mod1, nsim = 4)
## repeat the simulation:
.Random.seed <- attr(S1, "seed")
identical(S1, simulate(mod1, nsim = 4))

S2 <- simulate(mod1, nsim = 200, seed = 101)
rowMeans(S2) # should be about the same as
fitted(mod1)

## repeat identically:
(sseed <- attr(S2, "seed")) # seed; RNGkind as attribute
stopifnot(identical(S2, simulate(mod1, nsim = 200, seed = sseed)))

## To be sure about the proper RNGkind, e.g., after
RNGversion("2.7.0")
## first set the RNG kind, then simulate
do.call(RNGkind, attr(sseed, "kind"))
identical(S2, simulate(mod1, nsim = 200, seed = sseed))

## Binomial GLM examples
yb1 <- matrix(c(4, 4, 5, 7, 8, 6, 6, 5, 3, 2), ncol = 2)
modb1 <- glm(yb1 ~ x, family = binomial)
S3 <- simulate(modb1, nsim = 4)
# each column of S3 is a two-column matrix.

x2 <- sort(runif(100))
yb2 <- rbinom(100, prob = plogis(2*(x2-1)), size = 1)
yb2 <- factor(1 + yb2, labels = c("failure", "success"))
modb2 <- glm(yb2 ~ x2, family = binomial)
S4 <- simulate(modb2, nsim = 4)
# each column of S4 is a factor
```

## Description

Distribution function, quantile function and random generation for the distribution of the Smirnov statistic.

## Usage

```
psmirnov(q, sizes, z = NULL,
         alternative = c("two.sided", "less", "greater"),
         exact = TRUE, simulate = FALSE, B = 2000,
         lower.tail = TRUE, log.p = FALSE)
qsmirnov(p, sizes, z = NULL,
         alternative = c("two.sided", "less", "greater"),
         exact = TRUE, simulate = FALSE, B = 2000)
rsmirnov(n, sizes, z = NULL,
         alternative = c("two.sided", "less", "greater"))
```

## Arguments

|             |                                                                                                                                                                                             |
|-------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| q           | a numeric vector of quantiles.                                                                                                                                                              |
| p           | a numeric vector of probabilities.                                                                                                                                                          |
| sizes       | an integer vector of length two giving the sample sizes.                                                                                                                                    |
| z           | a numeric vector of the pooled data values in both samples when the exact conditional distribution of the Smirnov statistic given the data shall be computed.                               |
| alternative | one of "two.sided" (default), "less", or "greater" indicating whether absolute (two-sided, default) or raw (one-sided) differences of frequencies define the test statistic. See 'Details'. |
| exact       | NULL or a logical indicating whether the exact (conditional on the pooled data values in z) distribution or the asymptotic distribution should be used.                                     |
| simulate    | a logical indicating whether to compute the distribution function by Monte Carlo simulation.                                                                                                |
| B           | an integer specifying the number of replicates used in the Monte Carlo test.                                                                                                                |
| lower.tail  | a logical, if TRUE (default), probabilities are $P[D < q]$ , otherwise, $P[D \geq q]$ .                                                                                                     |
| log.p       | a logical, if TRUE (default), probabilities are given as log-probabilities.                                                                                                                 |
| n           | an integer giving number of observations.                                                                                                                                                   |

## Details

For samples  $x$  and  $y$  with respective sizes  $n_x$  and  $n_y$  and empirical cumulative distribution functions  $F_{x,n_x}$  and  $F_{y,n_y}$ , the Smirnov statistic is

$$D = \sup_c |F_{x,n_x}(c) - F_{y,n_y}(c)|$$

in the two-sided case,

$$D^+ = \sup_c (F_{x,n_x}(c) - F_{y,n_y}(c))$$

in the one-sided "greater" case, and

$$D^- = \sup_c (F_{y,n_y}(c) - F_{x,n_x}(c))$$

in the one-sided "less" case.

These statistics are used in the Smirnov test of the null that  $x$  and  $y$  were drawn from the same distribution, see [ks.test](#).

If the underlying common distribution function  $F$  is continuous, the distribution of the test statistics does not depend on  $F$ , and has a simple asymptotic approximation. For arbitrary  $F$ , one can compute the conditional distribution given the pooled data values  $z$  of  $x$  and  $y$ , either exactly (feasible provided that the product  $n_x n_y$  of the sample sizes is “small enough”) or approximately Monte Carlo simulation. If the pooled data values  $z$  are not specified, a pooled sample without ties is assumed.

Value

psmirnov gives the distribution function, qsmirnov gives the quantile function, and rsmirnov generates random deviates.

See Also

[ks.test](#) for references on the algorithms used for computing exact distributions.

---

|        |                                           |
|--------|-------------------------------------------|
| smooth | <i>Tukey's (Running Median) Smoothing</i> |
|--------|-------------------------------------------|

---

Description

Tukey's smoothers, *3RS3R*, *3RSS*, *3R*, etc.

Usage

```
smooth(x, kind = c("3RS3R", "3RSS", "3RSR", "3R", "3", "S"),
       twiceit = FALSE, endrule = c("Tukey", "copy"), do.ends = FALSE)
```

Arguments

|         |                                                                                                                                                                                                                 |
|---------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| x       | a vector or time series                                                                                                                                                                                         |
| kind    | a character string indicating the kind of smoother required; defaults to "3RS3R".                                                                                                                               |
| twiceit | logical, indicating if the result should be 'twiced'. Twicing a smoother $S(y)$ means $S(y) + S(y - S(y))$ , i.e., adding smoothed residuals to the smoothed values. This decreases bias (increasing variance). |
| endrule | a character string indicating the rule for smoothing at the boundary. Either "Tukey" (default) or "copy".                                                                                                       |
| do.ends | logical, indicating if the 3-splitting of ties should also happen at the boundaries (ends). This is only used for kind = "S".                                                                                   |

Details

3 is Tukey's short notation for running [medians](#) of length 3,  
3R stands for **R**epeated 3 until convergence, and  
S for **S**plitting of horizontal stretches of length 2 or 3.  
Hence, 3RS3R is a concatenation of 3R, S and 3R, 3RSS similarly, whereas 3RSR means first 3R and then (S and 3) **R**epeated until convergence – which can be bad.

**Value**

An object of class "tukeysmooth" (which has print and summary methods) and is a vector or time series containing the smoothed values with additional attributes.

**Note**

Note that there are other smoothing methods which provide rather better results. These were designed for hand calculations and may be used mainly for didactical purposes.

Since R version 1.2, smooth *does* really implement Tukey's end-point rule correctly (see argument `endrule`).

`kind = "3RSR"` had been the default till R-1.1, but it can have very bad properties, see the examples.

Note that repeated application of `smooth(*)` *does* smooth more, for the "3RS\*" kinds.

smooth.spline

*Fit a Smoothing Spline***Description**

Fits a cubic smoothing spline to the supplied data.

**Usage**

```
smooth.spline(x, y = NULL, w = NULL, df, spar = NULL, lambda = NULL, cv = FALSE,
              all.knots = FALSE, nknots = .nknots.smspl,
              keep.data = TRUE, df.offset = 0, penalty = 1,
              control.spar = list(), tol = 1e-6 * IQR(x), keep.stuff = FALSE)

.nknots.smspl(n)
```

**Arguments**

|           |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|-----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| x         | a vector giving the values of the predictor variable, or a list or a two-column matrix specifying x and y.                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| y         | responses. If y is missing or NULL, the responses are assumed to be specified by x, with x the index vector.                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| w         | optional vector of weights of the same length as x; defaults to all 1.                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| df        | the desired equivalent number of degrees of freedom (trace of the smoother matrix). Must be in $(1, n_x]$ , $n_x$ the number of unique x values, see below.                                                                                                                                                                                                                                                                                                                                                                                  |
| spar      | smoothing parameter, typically (but not necessarily) in $(0, 1]$ . When spar is specified, the coefficient $\lambda$ of the integral of the squared second derivative in the fit (penalized log likelihood) criterion is a monotone function of spar, see the details below. Alternatively lambda may be specified instead of the <i>scale free</i> $spar=s$ .                                                                                                                                                                               |
| lambda    | if desired, the internal (design-dependent) smoothing parameter $\lambda$ can be specified instead of spar. This may be desirable for resampling algorithms such as cross validation or the bootstrap.                                                                                                                                                                                                                                                                                                                                       |
| cv        | ordinary leave-one-out (TRUE) or ‘generalized’ cross-validation (GCV) when FALSE; is used for smoothing parameter computation only when both spar and df are not specified; it is used however to determine <code>cv.crit</code> in the result. Setting it to NA for speedup skips the evaluation of leverages and any score.                                                                                                                                                                                                                |
| all.knots | if TRUE, all distinct points in x are used as knots. If FALSE (default), a subset of <code>x[]</code> is used, specifically <code>x[j]</code> where the <code>nknots</code> indices are evenly spaced in <code>1:n</code> , see also the next argument <code>nknots</code> .<br><br>Alternatively, a strictly increasing <b>numeric</b> vector specifying “all the knots” to be used; must be rescaled to $[0, 1]$ already such that it corresponds to the <code>ans\$fit\$knots</code> sequence returned, not repeating the boundary knots. |
| nknots    | integer or <b>function</b> giving the number of knots to use when <code>all.knots = FALSE</code> . If a function (as by default), the number of knots is <code>nknots(nx)</code> . By default using <code>.nknots.smspl()</code> , for $n_x > 49$ this is less than $n_x$ , the number of unique x values, see the Note.                                                                                                                                                                                                                     |

|              |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|--------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| keep.data    | logical specifying if the input data should be kept in the result. If TRUE (as per default), fitted values and residuals are available from the result.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| df.offset    | allows the degrees of freedom to be increased by df.offset in the GCV criterion.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| penalty      | the coefficient of the penalty for degrees of freedom in the GCV criterion.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| control.spar | optional list with named components controlling the root finding when the smoothing parameter spar is computed, i.e., missing or NULL, see below.<br><b>Note</b> that this is partly <i>experimental</i> and may change with general spar computation improvements!<br><b>low:</b> lower bound for spar; defaults to -1.5 (used to implicitly default to 0 in R versions earlier than 1.4).<br><b>high:</b> upper bound for spar; defaults to +1.5.<br><b>tol:</b> the absolute precision ( <b>tolerance</b> ) used; defaults to 1e-4 (formerly 1e-3).<br><b>eps:</b> the relative precision used; defaults to 2e-8 (formerly 0.00244).<br><b>trace:</b> logical indicating if iterations should be traced.<br><b>maxit:</b> integer giving the maximal number of iterations; defaults to 500.<br>Note that spar is only searched for in the interval $[low, high]$ . |
| tol          | a tolerance for sameness or uniqueness of the x values. The values are binned into bins of size tol and values which fall into the same bin are regarded as the same. Must be strictly positive (and finite).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| keep.stuff   | an experimental <b>logical</b> indicating if the result should keep extras from the internal computations. Should allow to reconstruct the $X$ matrix and more.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| n            | for .nknots.smspl; typically the number of unique x values (aka $n_x$ ).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

## Details

Neither x nor y are allowed to containing missing or infinite values.

The x vector should contain at least four distinct values. ‘Distinct’ here is controlled by tol: values which are regarded as the same are replaced by the first of their values and the corresponding y and w are pooled accordingly.

Unless lambda has been specified instead of spar, the computational  $\lambda$  used (as a function of  $s = spar$ ) is  $\lambda = r \cdot 256^{3s-1}$  where  $r = tr(X'WX)/tr(\Sigma)$ ,  $\Sigma$  is the matrix given by  $\Sigma_{ij} = \int B_i''(t)B_j''(t)dt$ ,  $X$  is given by  $X_{ij} = B_j(x_i)$ ,  $W$  is the diagonal matrix of weights (scaled such that its trace is  $n$ , the original number of observations) and  $B_k(\cdot)$  is the  $k$ -th B-spline.

Note that with these definitions,  $f_i = f(x_i)$ , and the B-spline basis representation  $f = Xc$  (i.e.,  $c$  is the vector of spline coefficients), the penalized log likelihood is  $L = (y - f)'W(y - f) + \lambda c'\Sigma c$ , and hence  $c$  is the solution of the (ridge regression)  $(X'WX + \lambda\Sigma)c = X'Wy$ .

If spar and lambda are missing or NULL, the value of df is used to determine the degree of smoothing. If df is missing as well, leave-one-out cross-validation (ordinary or ‘generalized’ as determined by cv) is used to determine  $\lambda$ .

Note that from the above relation, spar is  $s = s_0 + 0.0601 \cdot \log \lambda$ .

Note however that currently the results may become very unreliable for spar values smaller than about -1 or -2. The same may happen for values larger than 2 or so. Don’t think of setting spar or the controls low and high outside such a safe range, unless you know what you are doing! Similarly, specifying lambda instead of spar is delicate, notably as the range of “safe” values for lambda is not scale-invariant and hence entirely data dependent.

The ‘generalized’ cross-validation method GCV will work correctly when there are duplicated points in  $x$ . However, it is ambiguous what leave-one-out cross-validation means with duplicated points, and the internal code uses an approximation that involves leaving out groups of duplicated points. `cv = TRUE` is best avoided in that case.

## Value

An object of class "smooth.spline" with components

|                       |                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|-----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>        | the <i>distinct</i> $x$ values in increasing order, see the ‘Details’ above.                                                                                                                                                                                                                                                                                                                                                                          |
| <code>y</code>        | the fitted values corresponding to $x$ .                                                                                                                                                                                                                                                                                                                                                                                                              |
| <code>w</code>        | the weights used at the unique values of $x$ .                                                                                                                                                                                                                                                                                                                                                                                                        |
| <code>yin</code>      | the $y$ values used at the unique $y$ values.                                                                                                                                                                                                                                                                                                                                                                                                         |
| <code>tol</code>      | the <code>tol</code> argument (whose default depends on $x$ ).                                                                                                                                                                                                                                                                                                                                                                                        |
| <code>data</code>     | only if <code>keep.data = TRUE</code> : itself a <a href="#">list</a> with components $x$ , $y$ and $w$ of the same length. These are the original $(x_i, y_i, w_i), i = 1, \dots, n$ , values where <code>data\$x</code> may have repeated values and hence be longer than the above $x$ component; see details.                                                                                                                                     |
| <code>n</code>        | an integer; the (original) sample size.                                                                                                                                                                                                                                                                                                                                                                                                               |
| <code>lev</code>      | (when <code>cv</code> was not NA) leverages, the diagonal values of the smoother matrix.                                                                                                                                                                                                                                                                                                                                                              |
| <code>cv</code>       | the <code>cv</code> argument used; i.e., FALSE, TRUE, or NA.                                                                                                                                                                                                                                                                                                                                                                                          |
| <code>cv.crit</code>  | cross-validation score, ‘generalized’ or true, depending on <code>cv</code> . The CV score is often called “PRESS” (and labeled on <a href="#">print()</a> ), for ‘ <b>P</b> REdiction <b>S</b> um of <b>S</b> quares’. Note that this is <i>not</i> the same as the (CV or GCV) score which is minimized during fitting (and returned in <code>crit</code> ), e.g., in the case of $n_x < n$ (where $n_x = n_x$ is the number of unique $x$ values). |
| <code>pen.crit</code> | the penalized criterion, a non-negative number; simply the (weighted) residual sum of squares (RSS), <code>sum(. \$w * residuals(.)^2)</code> .                                                                                                                                                                                                                                                                                                       |
| <code>crit</code>     | the criterion value minimized in the underlying <code>.Fortran</code> routine ‘ <code>sslvrg</code> ’. When <code>df</code> has been specified, the criterion is $3 + (tr(S_\lambda) - df)^2$ , where the <code>3+</code> is there for numerical (and historical) reasons.                                                                                                                                                                            |
| <code>df</code>       | equivalent degrees of freedom used. Note that (currently) this value may become quite imprecise when the true <code>df</code> is between and 1 and 2.                                                                                                                                                                                                                                                                                                 |
| <code>spar</code>     | the value of <code>spar</code> computed or given, unless it has been given as <code>c(lambda = *)</code> , when it set to NA here.                                                                                                                                                                                                                                                                                                                    |
| <code>ratio</code>    | (when <code>spar</code> above is not NA), the value $r$ , the ratio of two matrix traces.                                                                                                                                                                                                                                                                                                                                                             |
| <code>lambda</code>   | the value of $\lambda$ corresponding to <code>spar</code> , see the details above.                                                                                                                                                                                                                                                                                                                                                                    |
| <code>iparms</code>   | named integer(3) vector where <code>.. \$ipars["iter"]</code> gives number of <code>spar</code> computing iterations used.                                                                                                                                                                                                                                                                                                                            |
| <code>auxMat</code>   | experimental; when <code>keep.stuff</code> was true, a “flat” numeric vector containing parts of the internal computations.                                                                                                                                                                                                                                                                                                                           |
| <code>fit</code>      | list for use by <a href="#">predict.smooth.spline</a> , with components<br><b>knot</b> : the knot sequence (including the repeated boundary knots), scaled into $[0, 1]$ (via <code>min</code> and <code>range</code> ).<br><b>nk</b> : number of coefficients or number of ‘proper’ knots plus 2.<br><b>coef</b> : coefficients for the spline basis used.<br><b>min, range</b> : numbers giving the corresponding quantities of $x$ .               |
| <code>call</code>     | the matched call.                                                                                                                                                                                                                                                                                                                                                                                                                                     |

`method(class = "smooth.spline")` shows a [hatvalues\(\)](#) method based on the `lev` vector above.

**Note**

The number of unique  $x$  values,  $n_x = n_x$ , are determined by the `tol` argument, equivalently to

```
nx <- length(x) - sum(duplicated( round((x - mean(x)) / tol) ))
```

The default `all.knots = FALSE` and `nknots = .nknots.smspl`, entails using only  $O(n_x^{0.2})$  knots instead of  $n_x$  for  $n_x > 49$ . This cuts speed and memory requirements, but not drastically anymore since R version 1.5.1 where it is only  $O(n_k) + O(n)$  where  $n_k$  is the number of knots.

In this case where not all unique  $x$  values are used as knots, the result is a *regression spline* rather than a smoothing spline in the strict sense, but very close unless a small smoothing parameter (or large `df`) is used.

**Author(s)**

R implementation by B. D. Ripley and Martin Maechler (`spar/lambda`, etc).

**Source**

This function is based on code in the GAMFIT Fortran program by T. Hastie and R. Tibshirani (originally taken from <https://lib.stat.cmu.edu/general/gamfit>) which makes use of spline code by Finbarr O'Sullivan. Its design parallels the `smooth.spline` function of Chambers & Hastie (1992).

## Specifying 'lambda' instead of usual spar :
(s2. <- smooth.spline(y18, lambda = s2$lambda, tol = s2$tol))

## The following shows the problematic behavior of 'spar' searching:
(s2 <- smooth.spline(y18, control =
  list(trace = TRUE, tol = 1e-6, low = -1.5)))
(s2m <- smooth.spline(y18, cv = TRUE, control =
  list(trace = TRUE, tol = 1e-6, low = -1.5)))
## both above do quite similarly (Df = 8.5 +- 0.2)

```

---

smoothEnds

*End Points Smoothing (for Running Medians)*

---

## Description

Smooth end points of a vector  $y$  using subsequently smaller medians and Tukey's end point rule at the very end. (of odd span),

## Usage

```
smoothEnds(y, k = 3)
```

## Arguments

`y` dependent variable to be smoothed (vector).  
`k` width of largest median window; must be odd.

## Details

`smoothEnds` is used to only do the ‘end point smoothing’, i.e., change at most the observations closer to the beginning/end than half the window `k`. The first and last value are computed using *Tukey’s end point rule*, i.e., `sm[1] = median(y[1], sm[2], 3*sm[2] - 2*sm[3], na.rm=TRUE)`.

In R versions 3.6.0 and earlier, missing values (NA) in `y` typically lead to an error, whereas now the equivalent of `median(*, na.rm=TRUE)` is used.

## Value

vector of smoothed values, the same length as `y`.

## Author(s)

Martin Maechler

## References

## See Also

`runmed(*, endrule = "median")` which calls `smoothEnds()`.

## Examples

```
require(graphics)

y <- ys <- (-20:20)^2
y [c(1,10,21,41)] <- c(100, 30, 400, 470)
s7k <- runmed(y, 7, endrule = "keep")
s7. <- runmed(y, 7, endrule = "const")
s7m <- runmed(y, 7)
col3 <- c("midnightblue", "blue", "steelblue")
plot(y, main = "Running Medians -- runmed(*, k=7, endrule = X)")
lines(ys, col = "light gray")
matlines(cbind(s7k, s7., s7m), lwd = 1.5, lty = 1, col = col3)
eRules <- c("keep", "constant", "median")
legend("topleft", paste("endrule", eRules, sep = " = "),
       col = col3, lwd = 1.5, lty = 1, bty = "n")

stopifnot(identical(s7m, smoothEnds(s7k, 7)))

## With missing values (for R >= 3.6.1):
yN <- y; yN[c(2,40)] <- NA
rN <- sapply(eRules, function(R) runmed(yN, 7, endrule=R))
matlines(rN, type = "b", pch = 4, lwd = 3, lty=2,
        col = adjustcolor(c("red", "orange4", "orange1"), 0.5))
```

```

yN[c(1, 20:21)] <- NA # additionally
rN. <- sapply(eRules, function(R) runmed(yN, 7, endrule=R))
head(rN., 4); tail(rN.) # more NA's too, still not *so* many:
stopifnot(exprs = {
  !anyNA(rN[,2:3])
  identical(which(is.na(rN[, "keep"])), c(2L, 40L))
  identical(which(is.na(rN.), arr.ind=TRUE, useNames=FALSE),
             cbind(c(1:2,40L), 1L))
  identical(rN.[38:41, "median"], c(289,289, 397, 470))
})

```

sortedXyData

*Create a sortedXyData Object*

## Description

This is a constructor function for the class of sortedXyData objects. These objects are mostly used in the initial function for a self-starting nonlinear regression model, which will be of the selfStart class.

## Usage

```
sortedXyData(x, y, data)
```

## Arguments

|      |                                                                                                       |
|------|-------------------------------------------------------------------------------------------------------|
| x    | a numeric vector or an expression that will evaluate in data to a numeric vector                      |
| y    | a numeric vector or an expression that will evaluate in data to a numeric vector                      |
| data | an optional data frame in which to evaluate expressions for x and y, if they are given as expressions |

## Value

A sortedXyData object. This is a data frame with exactly two numeric columns, named x and y. The rows are sorted so the x column is in increasing order. Duplicate x values are eliminated by averaging the corresponding y values.

## Author(s)

José Pinheiro and Douglas Bates

## Examples

```

DNase.2 <- DNase[ DNase$Run == "2", ]
sortedXyData( expression(log(conc)), expression(density), DNase.2 )

```

spec.ar

*Estimate Spectral Density of a Time Series from AR Fit***Description**

Fits an AR model to `x` (or uses the existing fit) and computes (and by default plots) the spectral density of the fitted model.

**Usage**

```
spec.ar(x, n.freq, order = NULL, plot = TRUE, na.action = na.fail,
        method = "yule-walker", ...)
```

**Arguments**

|                        |                                                                                                   |
|------------------------|---------------------------------------------------------------------------------------------------|
| <code>x</code>         | A univariate (not yet:or multivariate) time series or the result of a fit by <a href="#">ar</a> . |
| <code>n.freq</code>    | The number of points at which to plot.                                                            |
| <code>order</code>     | The order of the AR model to be fitted. If omitted, the order is chosen by AIC.                   |
| <code>plot</code>      | Plot the periodogram?                                                                             |
| <code>na.action</code> | NA action function.                                                                               |
| <code>method</code>    | method for <a href="#">ar</a> fit.                                                                |
| <code>...</code>       | Graphical arguments passed to <a href="#">plot.spec</a> .                                         |

**Value**

An object of class "spec". The result is returned invisibly if `plot` is true.

**Warning**

Some authors, for example Thomson (1990), warn strongly that AR spectra can be misleading.

**Note**

The multivariate case is not yet implemented.

|            |                                                                             |
|------------|-----------------------------------------------------------------------------|
| spec.pgram | <i>Estimate Spectral Density of a Time Series by a Smoothed Periodogram</i> |
|------------|-----------------------------------------------------------------------------|

---

**Description**

spec.pgram calculates the periodogram using a fast Fourier transform, and optionally smooths the result with a series of modified Daniell smoothers (moving averages giving half weight to the end values).

**Usage**

```
spec.pgram(x, spans = NULL, kernel, taper = 0.1,
           pad = 0, fast = TRUE, demean = FALSE, detrend = TRUE,
           plot = TRUE, na.action = na.fail, ...)
```

**Arguments**

|           |                                                                                                                                                        |
|-----------|--------------------------------------------------------------------------------------------------------------------------------------------------------|
| x         | univariate or multivariate time series.                                                                                                                |
| spans     | vector of odd integers giving the widths of modified Daniell smoothers to be used to smooth the periodogram.                                           |
| kernel    | alternatively, a kernel smoother of class "tskernel".                                                                                                  |
| taper     | specifies the proportion of data to taper. A split cosine bell taper is applied to this proportion of the data at the beginning and end of the series. |
| pad       | proportion of data to pad. Zeros are added to the end of the series to increase its length by the proportion pad.                                      |
| fast      | logical; if TRUE, pad the series to a highly composite length.                                                                                         |
| demean    | logical. If TRUE, subtract the mean of the series.                                                                                                     |
| detrend   | logical. If TRUE, remove a linear trend from the series. This will also remove the mean.                                                               |
| plot      | plot the periodogram?                                                                                                                                  |
| na.action | NA action function.                                                                                                                                    |
| ...       | graphical arguments passed to plot.spec.                                                                                                               |

## Details

The raw periodogram is not a consistent estimator of the spectral density, but adjacent values are asymptotically independent. Hence a consistent estimator can be derived by smoothing the raw periodogram, assuming that the spectral density is smooth.

The series will be automatically padded with zeros until the series length is a highly composite number in order to help the Fast Fourier Transform. This is controlled by the `fast` and not the `pad` argument.

The periodogram at zero is in theory zero as the mean of the series is removed (but this may be affected by tapering): it is replaced by an interpolation of adjacent values during smoothing, and no value is returned for that frequency.

## Value

A list object of class "spec" (see [spectrum](#)) with the following additional components:

|                        |                                                                                                                                                      |
|------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>kernel</code>    | The kernel argument, or the kernel constructed from spans.                                                                                           |
| <code>df</code>        | The distribution of the spectral density estimate can be approximated by a (scaled) chi square distribution with <code>df</code> degrees of freedom. |
| <code>bandwidth</code> | The equivalent bandwidth of the kernel smoother as defined by Bloomfield (1976, page 201).                                                           |
| <code>taper</code>     | The value of the taper argument.                                                                                                                     |
| <code>pad</code>       | The value of the pad argument.                                                                                                                       |
| <code>detrend</code>   | The value of the detrend argument.                                                                                                                   |
| <code>demean</code>    | The value of the demean argument.                                                                                                                    |

The result is returned invisibly if `plot` is true.

spec.taper

*Taper a Time Series by a Cosine Bell***Description**

Apply a cosine-bell taper to a time series.

**Usage**

```
spec.taper(x, p = 0.1)
```

**Arguments**

|   |                                                                                                                                                                                                           |
|---|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| x | A univariate or multivariate time series                                                                                                                                                                  |
| p | The proportion to be tapered at each end of the series, either a scalar (giving the proportion for all series) or a vector of the length of the number of series (giving the proportion for each series). |

**Details**

The cosine-bell taper is applied to the first and last  $p[i]$  observations of time series  $x[, i]$ .

**Value**

A new time series object.

|----------|------------------------------------|
| spectrum | <i>Spectral Density Estimation</i> |
|----------|------------------------------------|

---

**Description**

The spectrum function estimates the spectral density of a time series.

**Usage**

```
spectrum(x, ..., method = c("pgram", "ar"))
```

**Arguments**

|        |                                                                                                                                             |
|--------|---------------------------------------------------------------------------------------------------------------------------------------------|
| x      | A univariate or multivariate time series.                                                                                                   |
| method | String specifying the method used to estimate the spectral density. Allowed methods are "pgram" (the default) and "ar". Can be abbreviated. |
| ...    | Further arguments to specific spec methods or plot.spec.                                                                                    |

**Details**

spectrum is a wrapper function which calls the methods [spec.pgram](#) and [spec.ar](#).  
The spectrum here is defined (for historical compatibility) with scaling  $1/\text{frequency}(x)$ . This makes the spectral density a density over the range  $(-\text{frequency}(x)/2, +\text{frequency}(x)/2]$ , whereas a more common scaling is  $2\pi$  and range  $(-0.5, 0.5]$  (e.g., Bloomfield) or 1 and range  $(-\pi, \pi]$ .  
If available, a confidence interval will be plotted by `plot.spec`: this is asymmetric, and the width of the centre mark indicates the equivalent bandwidth.

**Value**

An object of class "spec", which is a list containing at least the following components:

|        |                                                                                                                                                                                                                                                               |
|--------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| freq   | vector of frequencies at which the spectral density is estimated. (Possibly approximate Fourier frequencies.) The units are the reciprocal of cycles per unit time (and not per observation spacing): see 'Details' below.                                    |
| spec   | Vector (for univariate series) or matrix (for multivariate series) of estimates of the spectral density at frequencies corresponding to freq.                                                                                                                 |
| coh    | NULL for univariate series. For multivariate time series, a matrix containing the <i>squared</i> coherency between different series. Column $i + (j - 1) * (j - 2)/2$ of coh contains the squared coherency between columns $i$ and $j$ of x, where $i < j$ . |
| phase  | NULL for univariate series. For multivariate time series a matrix containing the cross-spectrum phase between different series. The format is the same as coh.                                                                                                |
| series | The name of the time series.                                                                                                                                                                                                                                  |
| snames | For multivariate input, the names of the component series.                                                                                                                                                                                                    |
| method | The method used to calculate the spectrum.                                                                                                                                                                                                                    |

The result is returned invisibly if plot is true.

**Note**

The default plot for objects of class "spec" is quite complex, including an error bar and default title, subtitle and axis labels. The defaults can all be overridden by supplying the appropriate graphical parameters.

spectrum(lh, method = "ar")
spectrum(ldeaths, method = "ar")
```

**Description**

Perform cubic (or Hermite) spline interpolation of given data points, returning either a list of points obtained by the interpolation or a *function* performing the interpolation.

## Usage

```
splinefun(x, y = NULL,
          method = c("fmm", "periodic", "natural", "monoH.FC", "hyman"),
          ties = mean)

spline(x, y = NULL, n = 3*length(x), method = "fmm",
       xmin = min(x), xmax = max(x), xout, ties = mean)

splinefunH(x, y, m)
```

## Arguments

|                         |                                                                                                                                                                                                                                                                                  |
|-------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x, y</code>       | vectors giving the coordinates of the points to be interpolated. Alternatively a single plotting structure can be specified: see <a href="#">xy.coords</a> .<br>y must be increasing or decreasing for <code>method = "hyman"</code> .                                           |
| <code>m</code>          | (for <code>splinefunH()</code> ): vector of <i>slopes</i> $m_i$ at the points $(x_i, y_i)$ ; these together determine the <b>H</b> ermite “spline” which is piecewise cubic, (only) <i>once</i> differentiable continuously.                                                     |
| <code>method</code>     | specifies the type of spline to be used. Possible values are "fmm", "natural", "periodic", "monoH.FC" and "hyman". Can be abbreviated.                                                                                                                                           |
| <code>n</code>          | if <code>xout</code> is left unspecified, interpolation takes place at <code>n</code> equally spaced points spanning the interval <code>[xmin, xmax]</code> .                                                                                                                    |
| <code>xmin, xmax</code> | left-hand and right-hand endpoint of the interpolation interval (when <code>xout</code> is unspecified).                                                                                                                                                                         |
| <code>xout</code>       | an optional set of values specifying where interpolation is to take place.                                                                                                                                                                                                       |
| <code>ties</code>       | handling of tied x values. The string "ordered" or a function (or the name of a function) taking a single vector argument and returning a single number or a length-2 <a href="#">list</a> of both, see <a href="#">approx</a> and its ‘Details’ section, and the example below. |

## Details

The inputs can contain missing values which are deleted, so at least one complete (x, y) pair is required. If `method = "fmm"`, the spline used is that of Forsythe, Malcolm and Moler (an exact cubic is fitted through the four points at each end of the data, and this is used to determine the end conditions). Natural splines are used when `method = "natural"`, and periodic splines when `method = "periodic"`.

The method "monoH.FC" computes a *monotone* Hermite spline according to the method of Fritsch and Carlson. It does so by determining slopes such that the Hermite spline, determined by  $(x_i, y_i, m_i)$ , is monotone (increasing or decreasing) **iff** the data are.

Method "hyman" computes a *monotone* cubic spline using Hyman filtering of an `method = "fmm"` fit for strictly monotonic inputs.

These interpolation splines can also be used for extrapolation, that is prediction at points outside the range of x. Extrapolation makes little sense for `method = "fmm"`; for natural splines it is linear using the slope of the interpolating curve at the nearest data point.

## Value

`spline` returns a list containing components `x` and `y` which give the ordinates where interpolation took place and the interpolated values.

splinefun returns a function with formal arguments `x` and `deriv`, the latter defaulting to zero. This function can be used to evaluate the interpolating cubic spline (`deriv = 0`), or its derivatives (`deriv = 1, 2, 3`) at the points `x`, where the spline function interpolates the data points originally specified. It uses data stored in its environment when it was created, the details of which are subject to change.

### Warning

The value returned by `splinefun` contains references to the code in the current version of R: it is not intended to be saved and loaded into a different R session. This is safer in R  $\geq$  3.0.0.

### Author(s)

R Core Team.

Simon Wood for the original code for Hyman filtering.

## here, and both are 'much worse' than the regular fmm spline.

```

SSasymp

*Self-Starting nls Asymptotic Model*

## Description

This `selfStart` model evaluates the asymptotic regression function and its gradient. It has an initial attribute that will evaluate initial estimates of the parameters `Asym`, `R0`, and `lrc` for a given set of data.

Note that `SSweibull()` generalizes this asymptotic model with an extra parameter.

## Usage

```
SSasymp(input, Asym, R0, lrc)
```

## Arguments

|                    |                                                                                                           |
|--------------------|-----------------------------------------------------------------------------------------------------------|
| <code>input</code> | a numeric vector of values at which to evaluate the model.                                                |
| <code>Asym</code>  | a numeric parameter representing the horizontal asymptote on the right side (very large values of input). |
| <code>R0</code>    | a numeric parameter representing the response when input is zero.                                         |
| <code>lrc</code>   | a numeric parameter representing the natural logarithm of the rate constant.                              |

**Value**

a numeric vector of the same length as input. It is the value of the expression  $\text{Asym} + (R0 - \text{Asym}) * \exp(-\exp(lrc) * \text{input})$ . If all of the arguments `Asym`, `R0`, and `lrc` are names of objects, the gradient matrix with respect to these names is attached as an attribute named `gradient`.

SSasymptOff

*Self-Starting nls Asymptotic Model with an Offset*

## Description

This `selfStart` model evaluates an alternative parametrization of the asymptotic regression function and the gradient with respect to those parameters. It has an `initial` attribute that creates initial estimates of the parameters `Asym`, `lrc`, and `c0`.

## Usage

```
SSasymptOff(input, Asym, lrc, c0)
```

## Arguments

|                    |                                                                                                           |
|--------------------|-----------------------------------------------------------------------------------------------------------|
| <code>input</code> | a numeric vector of values at which to evaluate the model.                                                |
| <code>Asym</code>  | a numeric parameter representing the horizontal asymptote on the right side (very large values of input). |
| <code>lrc</code>   | a numeric parameter representing the natural logarithm of the rate constant.                              |
| <code>c0</code>    | a numeric parameter representing the input for which the response is zero.                                |

## Value

a numeric vector of the same length as `input`. It is the value of the expression `Asym*(1 - exp(-exp(lrc)*(input - c0)))`. If all of the arguments `Asym`, `lrc`, and `c0` are names of objects, the gradient matrix with respect to these names is attached as an attribute named `gradient`.

SSbiexp

*Self-Starting nls Biexponential Model***Description**

This selfStart model evaluates the biexponential model function and its gradient. It has an initial attribute that creates initial estimates of the parameters A1, lrc1, A2, and lrc2.

**Usage**

```
SSbiexp(input, A1, lrc1, A2, lrc2)
```

**Arguments**

|                    |                                                                                                        |
|--------------------|--------------------------------------------------------------------------------------------------------|
| <code>input</code> | a numeric vector of values at which to evaluate the model.                                             |
| <code>A1</code>    | a numeric parameter representing the multiplier of the first exponential.                              |
| <code>lrc1</code>  | a numeric parameter representing the natural logarithm of the rate constant of the first exponential.  |
| <code>A2</code>    | a numeric parameter representing the multiplier of the second exponential.                             |
| <code>lrc2</code>  | a numeric parameter representing the natural logarithm of the rate constant of the second exponential. |

**Value**

a numeric vector of the same length as `input`. It is the value of the expression  $A1 \cdot \exp(-\exp(lrc1) \cdot \text{input}) + A2 \cdot \exp(-\exp(lrc2) \cdot \text{input})$ . If all of the arguments `A1`, `lrc1`, `A2`, and `lrc2` are names of objects, the gradient matrix with respect to these names is attached as an attribute named `gradient`.

SSD

*SSD Matrix and Estimated Variance Matrix in Multivariate Models***Description**

Functions to compute matrix of residual sums of squares and products, or the estimated variance matrix for multivariate linear models.

**Usage**

```
# S3 method for class 'mlm'
SSD(object, ...)

# S3 methods for class 'SSD' and 'mlm'
estVar(object, ...)
```

**Arguments**

|        |                                                        |
|--------|--------------------------------------------------------|
| object | object of class "mlm", or "SSD" in the case of estVar. |
| ...    | Unused                                                 |

**Value**

SSD() returns a list of class "SSD" containing the following components

|      |                                                  |
|------|--------------------------------------------------|
| SSD  | The residual sums of squares and products matrix |
| df   | Degrees of freedom                               |
| call | Copied from object                               |

estVar returns a matrix with the estimated variances and covariances.

|-------|--------------------------------------------------------|
| SSfol | <i>Self-Starting nls First-order Compartment Model</i> |
|-------|--------------------------------------------------------|

---

Description

This selfStart model evaluates the first-order compartment function and its gradient. It has an initial attribute that creates initial estimates of the parameters lKe, lKa, and lCl.

Usage

```
SSfol(Dose, input, lKe, lKa, lCl)
```

Arguments

|       |                                                                                          |
|-------|------------------------------------------------------------------------------------------|
| Dose  | a numeric value representing the initial dose.                                           |
| input | a numeric vector at which to evaluate the model.                                         |
| lKe   | a numeric parameter representing the natural logarithm of the elimination rate constant. |
| lKa   | a numeric parameter representing the natural logarithm of the absorption rate constant.  |
| lCl   | a numeric parameter representing the natural logarithm of the clearance.                 |

**Value**

a numeric vector of the same length as input, which is the value of the expression

$$\text{Dose} * \exp(\text{lKe} + \text{lKa} - \text{lCl}) * (\exp(-\exp(\text{lKe}) * \text{input}) - \exp(-\exp(\text{lKa}) * \text{input})) / (\exp(\text{lKa}) - \exp(\text{lKe}))$$

If all of the arguments lKe, lKa, and lCl are names of objects, the gradient matrix with respect to these names is attached as an attribute named gradient.

SSfpl

*Self-Starting nls Four-Parameter Logistic Model*

---

**Description**

This selfStart model evaluates the four-parameter logistic function and its gradient. It has an initial attribute computing initial estimates of the parameters A, B, xmid, and scal for a given set of data.

**Usage**

```
SSfpl(input, A, B, xmid, scal)
```

**Arguments**

|       |                                                                                                                                                   |
|-------|---------------------------------------------------------------------------------------------------------------------------------------------------|
| input | a numeric vector of values at which to evaluate the model.                                                                                        |
| A     | a numeric parameter representing the horizontal asymptote on the left side (very small values of input).                                          |
| B     | a numeric parameter representing the horizontal asymptote on the right side (very large values of input).                                         |
| xmid  | a numeric parameter representing the input value at the inflection point of the curve. The value of SSfpl will be midway between A and B at xmid. |
| scal  | a numeric scale parameter on the input axis.                                                                                                      |

**Value**

a numeric vector of the same length as input. It is the value of the expression  $A + (B - A) / (1 + \exp((x_{\text{mid}} - \text{input}) / \text{scal}))$ . If all of the arguments A, B, xmid, and scal are names of objects, the gradient matrix with respect to these names is attached as an attribute named gradient.

SSgompertz

*Self-Starting nls Gompertz Growth Model***Description**

This selfStart model evaluates the Gompertz growth model and its gradient. It has an initial attribute that creates initial estimates of the parameters Asym, b2, and b3.

**Usage**

```
SSgompertz(x, Asym, b2, b3)
```

**Arguments**

|      |                                                                     |
|------|---------------------------------------------------------------------|
| x    | a numeric vector of values at which to evaluate the model.          |
| Asym | a numeric parameter representing the asymptote.                     |
| b2   | a numeric parameter related to the value of the function at $x = 0$ |
| b3   | a numeric parameter related to the scale the x axis.                |

**Value**

a numeric vector of the same length as input. It is the value of the expression  $\text{Asym} \cdot \exp(-b2 \cdot b3^x)$ . If all of the arguments Asym, b2, and b3 are names of objects the gradient matrix with respect to these names is attached as an attribute named gradient.

SSlogis

*Self-Starting nls Logistic Model*

---

## Description

This `selfStart` model evaluates the logistic function and its gradient. It has an `initial` attribute that creates initial estimates of the parameters `Asym`, `xmid`, and `scal`. In R 3.4.2 and earlier, that `init` function failed when `min(input)` was exactly zero.

## Usage

```
SSlogis(input, Asym, xmid, scal)
```

## Arguments

|                    |                                                                                                                                                                           |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>input</code> | a numeric vector of values at which to evaluate the model.                                                                                                                |
| <code>Asym</code>  | a numeric parameter representing the asymptote.                                                                                                                           |
| <code>xmid</code>  | a numeric parameter representing the $x$ value at the inflection point of the curve. The value of <code>SSlogis</code> will be <code>Asym/2</code> at <code>xmid</code> . |
| <code>scal</code>  | a numeric scale parameter on the input axis.                                                                                                                              |

## Value

a numeric vector of the same length as `input`. It is the value of the expression  $\text{Asym}/(1+\exp((\text{xmid}-\text{input})/\text{scal}))$ . If all of the arguments `Asym`, `xmid`, and `scal` are names of objects the gradient matrix with respect to these names is attached as an attribute named `gradient`.

SSmicmen

*Self-Starting nls Michaelis-Menten Model***Description**

This selfStart model evaluates the Michaelis-Menten model and its gradient. It has an initial attribute that will evaluate initial estimates of the parameters Vm and K

**Usage**

```
SSmicmen(input, Vm, K)
```

**Arguments**

|       |                                                                                                                                                                          |
|-------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| input | a numeric vector of values at which to evaluate the model.                                                                                                               |
| Vm    | a numeric parameter representing the maximum value of the response.                                                                                                      |
| K     | a numeric parameter representing the input value at which half the maximum response is attained. In the field of enzyme kinetics this is called the Michaelis parameter. |

**Value**

a numeric vector of the same length as input. It is the value of the expression  $V_m \times \text{input} / (K + \text{input})$ . If both the arguments  $V_m$  and  $K$  are names of objects, the gradient matrix with respect to these names is attached as an attribute named `gradient`.

text(1, 2.7, quote(phi[2]))
par(op)
```

## Description

This `selfStart` model evaluates the Weibull model for growth curve data and its gradient. It has an `initial` attribute that will evaluate initial estimates of the parameters `Asym`, `Drop`, `lrc`, and `pwr` for a given set of data.

## Usage

```
SSweibull(x, Asym, Drop, lrc, pwr)
```

## Arguments

|                   |                                                                                                                     |
|-------------------|---------------------------------------------------------------------------------------------------------------------|
| <code>x</code>    | a numeric vector of values at which to evaluate the model.                                                          |
| <code>Asym</code> | a numeric parameter representing the horizontal asymptote on the right side (very small values of <code>x</code> ). |
| <code>Drop</code> | a numeric parameter representing the change from <code>Asym</code> to the <code>y</code> intercept.                 |
| <code>lrc</code>  | a numeric parameter representing the natural logarithm of the rate constant.                                        |
| <code>pwr</code>  | a numeric parameter representing the power to which <code>x</code> is raised.                                       |

## Details

This model is a generalization of the [SSasymp](#) model in that it reduces to `SSasymp` when `pwr` is unity.

## Value

a numeric vector of the same length as `x`. It is the value of the expression  $\text{Asym} - \text{Drop} \times \exp(-\exp(\text{lrc}) \times x^{\text{pwr}})$ . If all of the arguments `Asym`, `Drop`, `lrc`, and `pwr` are names of objects, the gradient matrix with respect to these names is attached as an attribute named `gradient`.

start

*Encode the Terminal Times of Time Series*

---

## Description

Extract and encode the times the first and last observations were taken. Provided only for compatibility with S version 2.

## Usage

```
start(x, ...)
end(x, ...)
```

## Arguments

|     |                                                                  |
|-----|------------------------------------------------------------------|
| x   | a univariate or multivariate time-series, or a vector or matrix. |
| ... | extra arguments for future methods.                              |

## Details

These are generic functions, which will use the `tsp` attribute of `x` if it exists. Their default methods decode the start time from the original time units, so that for a monthly series 1995.5 is represented as `c(1995, 7)`. For a series of frequency `f`, time `n+i/f` is presented as `c(n, i+1)` (even for `i = 0` and `f = 1`).

## Warning

The representation used by `start` and `end` has no meaning unless the frequency is supplied.

## See Also

`ts`, `time`, `tsp`.

stat.anova

GLM ANOVA Statistics

**Description**

This is a utility function, used in `lm` and `glm` methods for `anova(..., test != NULL)` and should not be used by the average user.

**Usage**

```
stat.anova(table, test = c("Rao", "LRT", "Chisq", "F", "Cp"),
           scale, df.scale, n)
```

**Arguments**

|                       |                                                                                            |
|-----------------------|--------------------------------------------------------------------------------------------|
| <code>table</code>    | numeric matrix as results from <code>anova.glm(..., test = NULL)</code> .                  |
| <code>test</code>     | a character string, partially matching one of "Rao", "LRT", "Chisq", "F" or "Cp".          |
| <code>scale</code>    | a residual mean square or other scale estimate to be used as the denominator in an F test. |
| <code>df.scale</code> | degrees of freedom corresponding to scale.                                                 |
| <code>n</code>        | number of observations.                                                                    |

**Value**

A matrix which is the original table, augmented by a column of test statistics, depending on the `test` argument.

|      |                                                      |
|------|------------------------------------------------------|
| step | <i>Choose a model by AIC in a Stepwise Algorithm</i> |
|------|------------------------------------------------------|

---

**Description**

Select a formula-based model by AIC.

**Usage**

```
step(object, scope, scale = 0,
      direction = c("both", "backward", "forward"),
      trace = 1, keep = NULL, steps = 1000, k = 2, ...)
```

**Arguments**

|           |                                                                                                                                                                                                                                                                   |
|-----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| object    | an object representing a model of an appropriate class (mainly "lm" and "glm"). This is used as the initial model in the stepwise search.                                                                                                                         |
| scope     | defines the range of models examined in the stepwise search. This should be either a single formula, or a list containing components upper and lower, both formulae. See the details for how to specify the formulae and how they are used.                       |
| scale     | used in the definition of the AIC statistic for selecting the models, currently only for <a href="#">lm</a> , <a href="#">aov</a> and <a href="#">glm</a> models. The default value, 0, indicates the scale should be estimated: see <a href="#">extractAIC</a> . |
| direction | the mode of stepwise search, can be one of "both", "backward", or "forward", with a default of "both". If the scope argument is missing the default for direction is "backward". Values can be abbreviated.                                                       |
| trace     | if positive, information is printed during the running of step. Larger values may give more detailed information.                                                                                                                                                 |
| keep      | a filter function whose input is a fitted model object and the associated AIC statistic, and whose output is arbitrary. Typically keep will select a subset of the components of the object and return them. The default is not to keep anything.                 |

|       |                                                                                                                                                                  |
|-------|------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| steps | the maximum number of steps to be considered. The default is 1000 (essentially as many as required). It is typically used to stop the process early.             |
| k     | the multiple of the number of degrees of freedom used for the penalty. Only $k = 2$ gives the genuine AIC: $k = \log(n)$ is sometimes referred to as BIC or SBC. |
| ...   | any additional arguments to <code>extractAIC</code> .                                                                                                            |

## Details

step uses `add1` and `drop1` repeatedly; it will work for any method for which they work, and that is determined by having a valid method for `extractAIC`. When the additive constant can be chosen so that AIC is equal to Mallows'  $C_p$ , this is done and the tables are labelled appropriately.

The set of models searched is determined by the scope argument. The right-hand-side of its lower component is always included in the model, and right-hand-side of the model is included in the upper component. If scope is a single formula, it specifies the upper component, and the lower model is empty. If scope is missing, the initial model is used as the upper model.

Models specified by scope can be templates to update object as used by `update.formula`. So using `.` in a scope formula means 'what is already there', with `.^2` indicating all interactions of existing terms.

There is a potential problem in using `glm` fits with a variable scale, as in that case the deviance is not simply related to the maximized log-likelihood. The "glm" method for function `extractAIC` makes the appropriate adjustment for a gaussian family, but may need to be amended for other cases. (The binomial and poisson families have fixed scale by default and do not correspond to a particular maximum-likelihood problem for variable scale.)

## Value

the stepwise-selected model is returned, with up to two additional components. There is an "anova" component corresponding to the steps taken in the search, as well as a "keep" component if the `keep=` argument was supplied in the call. The "Resid. Dev" column of the analysis of deviance table refers to a constant minus twice the maximized log likelihood: it will be a deviance only in cases where a saturated model is well-defined (thus excluding `lm`, `aov` and `survreg` fits, for example).

## Warning

The model fitting must apply the models to the same dataset. This may be a problem if there are missing values and R's default of `na.action = na.omit` is used. We suggest you remove the missing values first.

Calls to the function `nobs` are used to check that the number of observations involved in the fitting process remains unchanged.

## Note

This function differs considerably from the function in S, which uses a number of approximations and does not in general compute the correct AIC.

This is a minimal implementation. Use `stepAIC` in package **MASS** for a wider range of object classes.

**Author(s)**

B. D. Ripley: step is a slightly simplified version of [stepAIC](#) in package **MASS** (Venables & Ripley, 2002 and earlier editions).

The idea of a step function follows that described in Hastie & Pregibon (1992); but the implementation in R is more general.

stepfun

---

*Step Functions - Creation and Class*

---

**Description**

Given the vectors  $(x_1, \dots, x_n)$  and  $(y_0, y_1, \dots, y_n)$  (one value more!), `stepfun(x, y, ...)` returns an interpolating ‘step’ function, say `fn`. I.e.,  $fn(t) = c_i$  (constant) for  $t \in (x_i, x_{i+1})$  and at the abscissa values, if (by default) `right = FALSE`,  $fn(x_i) = y_i$  and for `right = TRUE`,  $fn(x_i) = y_{i-1}$ , for  $i = 1, \dots, n$ .

The value of the constant  $c_i$  above depends on the ‘continuity’ parameter `f`. For the default, `right = FALSE`,  $f = 0$ , `fn` is a *cadlag* function, i.e., continuous from the right, limits from the left, so that the function is piecewise constant on intervals that include their *left* endpoint. In general,  $c_i$  is interpolated in between the neighbouring  $y$  values,  $c_i = (1 - f)y_i + f \cdot y_{i+1}$ . Therefore, for non-0 values of `f`, `fn` may no longer be a proper step function, since it can be discontinuous from both sides, unless `right = TRUE`,  $f = 1$  which is left-continuous (i.e., constant pieces contain their right endpoint).

**Usage**

```

stepfun(x, y, f = as.numeric(right), ties = "ordered",
        right = FALSE)

is.stepfun(x)
knots(Fn, ...)
as.stepfun(x, ...)

## S3 method for class 'stepfun'
print(x, digits = getOption("digits") - 2, ...)

## S3 method for class 'stepfun'
summary(object, ...)

```

**Arguments**

|            |                                                                                                                                                    |
|------------|----------------------------------------------------------------------------------------------------------------------------------------------------|
| x          | numeric vector giving the knots or jump locations of the step function for <code>stepfun()</code> . For the other functions, x is as object below. |
| y          | numeric vector one longer than x, giving the heights of the function values <i>between</i> the x values.                                           |
| f          | a number between 0 and 1, indicating how interpolation outside the given x values should happen. See <a href="#">approxfun</a> .                   |
| ties       | Handling of tied x values. Either a function or the string "ordered". See <a href="#">approxfun</a> .                                              |
| right      | logical, indicating if the intervals should be closed on the right (and open on the left) or vice versa.                                           |
| Fn, object | an R object inheriting from "stepfun".                                                                                                             |
| digits     | number of significant digits to use, see <a href="#">print</a> .                                                                                   |
| ...        | potentially further arguments (required by the generic).                                                                                           |

**Value**

A function of class "stepfun", say `fn`.

There are methods available for summarizing ("`summary(.)`"), representing ("`print(.)`") and plotting ("`plot(.)`", see [plot.stepfun](#)) "stepfun" objects.

The [environment](#) of `fn` contains all the information needed;

|                   |                                                             |
|-------------------|-------------------------------------------------------------|
| "x", "y"          | the original arguments                                      |
| "n"               | number of knots (x values)                                  |
| "f"               | continuity parameter                                        |
| "yleft", "yright" | the function values <i>outside</i> the knots                |
| "method"          | (always == "constant", from <a href="#">approxfun(.)</a> ). |

The knots are also available via `knots(fn)`.

**Note**

The objects of class "stepfun" are not intended to be used for permanent storage and may change structure between versions of R (and did at R 3.0.0). They can usually be re-created by

```
eval(attr(old_obj, "call"), environment(old_obj))
```

since the data used is stored as part of the object's environment.

|------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| x                      | univariate time series to be decomposed. This should be an object of class "ts" with a frequency greater than one.                                                                                                                                                                                                                                   |
| s.window               | either the character string "periodic" or the span (in lags) of the loess window for seasonal extraction, which should be odd and at least 7, according to Cleveland et al. This has no default.                                                                                                                                                     |
| s.degree               | degree of locally-fitted polynomial in seasonal extraction. Should be zero or one.                                                                                                                                                                                                                                                                   |
| t.window               | the span (in lags) of the loess window for trend extraction, which should be odd. If NULL, the default, <code>nextodd(ceiling((1.5*period) / (1-(1.5/s.window))))</code> , is taken.                                                                                                                                                                 |
| t.degree               | degree of locally-fitted polynomial in trend extraction. Should be zero or one.                                                                                                                                                                                                                                                                      |
| l.window               | the span (in lags) of the loess window of the low-pass filter used for each subseries. Defaults to the smallest odd integer greater than or equal to <code>frequency(x)</code> which is recommended since it prevents competition between the trend and seasonal components. If not an odd integer its given value is increased to the next odd one. |
| l.degree               | degree of locally-fitted polynomial for the subseries low-pass filter. Must be 0 or 1.                                                                                                                                                                                                                                                               |
| s.jump, t.jump, l.jump | integers at least one to increase speed of the respective smoother. Linear interpolation happens between every *.jump-th value.                                                                                                                                                                                                                      |
| robust                 | logical indicating if robust fitting be used in the loess procedure.                                                                                                                                                                                                                                                                                 |
| inner                  | integer; the number of 'inner' (backfitting) iterations; usually very few (2) iterations suffice.                                                                                                                                                                                                                                                    |
| outer                  | integer; the number of 'outer' robustness iterations.                                                                                                                                                                                                                                                                                                |
| na.action              | action on missing values.                                                                                                                                                                                                                                                                                                                            |

## Details

The seasonal component is found by *loess* smoothing the seasonal sub-series (the series of all January values, ...); if `s.window = "periodic"` smoothing is effectively replaced by taking the mean. The seasonal values are removed, and the remainder smoothed to find the trend. The overall level is removed from the seasonal component and added to the trend component. This process is iterated a few times. The remainder component is the residuals from the seasonal plus trend fit.

Several methods for the resulting class "stl" objects, see, [plot.stl](#).

**Value**

stl returns an object of class "stl" with components

|             |                                                                                    |
|-------------|------------------------------------------------------------------------------------|
| time.series | a multiple time series with columns seasonal, trend and remainder.                 |
| weights     | the final robust weights (all one if fitting is not done robustly).                |
| call        | the matched call.                                                                  |
| win         | integer (length 3 vector) with the spans used for the "s", "t", and "l" smoothers. |
| deg         | integer (length 3) vector with the polynomial degrees for these smoothers.         |
| jump        | integer (length 3) vector with the 'jumps' (skips) used for these smoothers.       |
| ni          | number of <b>inner</b> iterations                                                  |
| no          | number of <b>outer</b> robustness iterations                                       |

[StructTS](#) for different kind of decomposition.

**Examples**

```
require(graphics)

plot(stl(nottem, "per"))
plot(stl(nottem, s.window = 7, t.window = 50, t.jump = 1))

plot(stllc <- stl(log(co2), s.window = 21))
summary(stllc)
## linear trend, strict period.
plot(stl(log(co2), s.window = "per", t.window = 1000))

## Two STL plotted side by side :
stmd <- stl(mdeaths, s.window = "per") # non-robust
summary(stmR <- stl(mdeaths, s.window = "per", robust = TRUE))
op <- par(mar = c(0, 4, 0, 3), oma = c(5, 0, 4, 0), mfcol = c(4, 2))
plot(stmd, set.pars = NULL, labels = NULL,
     main = "stl(mdeaths, s.w = \"per\", robust = FALSE / TRUE)")
plot(stmR, set.pars = NULL)
# mark the 'outliers' :
(i0 <- which(stmR $ weights < 1e-8)) # 10 were considered outliers
sts <- stmR$time.series
points(time(sts)[i0], 0.8* sts[, "remainder"][i0], pch = 4, col = "red")
par(op) # reset
```

## Description

Methods for objects of class `stl`, typically the result of `stl`. The `plot` method does a multiple figure plot with some flexibility.

There are also (non-visible) `print` and `summary` methods.

## Usage

```
## S3 method for class 'stl'
plot(x, labels = colnames(X),
     set.pars = list(mar = c(0, 6, 0, 6), oma = c(6, 0, 4, 0),
                    tck = -0.01, mfrow = c(nplot, 1)),
     main = NULL, range.bars = TRUE, ...,
     col.range = "light gray")

## S3 method for class 'stl'
summary(object, digits = max(3L, getOption("digits") - 3L), ...)
```

## Arguments

|                         |                                                                                                                                          |
|-------------------------|------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x, object</code>  | <code>stl</code> object.                                                                                                                 |
| <code>labels</code>     | character of length 4 giving the names of the component time-series.                                                                     |
| <code>set.pars</code>   | settings for <code>par(.)</code> when setting up the plot.                                                                               |
| <code>main</code>       | plot main title.                                                                                                                         |
| <code>range.bars</code> | logical indicating if each plot should have a bar at its right side which are of equal heights in user coordinates.                      |
| <code>col.range</code>  | colour to be used for the range bars, if plotted. Note this appears after <code>...</code> and so cannot be abbreviated.                 |
| <code>...</code>        | further arguments passed to or from other methods; for <code>summary()</code> , e.g., <code>zdigits</code> passed to the default method. |
| <code>digits</code>     | passed to the default <code>summary</code> method (for <code>time.series</code> and <code>weights</code> components).                    |

## See Also

`plot.ts` and `stl`, particularly for examples; `summary.default`.

## Description

Fit a structural model for a time series by maximum likelihood.

## Usage

```
StructTS(x, type = c("level", "trend", "BSM"), init = NULL,
         fixed = NULL, optim.control = NULL)
```

## Arguments

|                            |                                                                                                                                                                                                      |
|----------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>             | a univariate numeric time series. Missing values are allowed.                                                                                                                                        |
| <code>type</code>          | the class of structural model. If omitted, a BSM is used for a time series with $\text{frequency}(x) > 1$ , and a local trend model otherwise. Can be abbreviated.                                   |
| <code>init</code>          | initial values of the variance parameters.                                                                                                                                                           |
| <code>fixed</code>         | optional numeric vector of the same length as the total number of parameters. If supplied, only NA entries in <code>fixed</code> will be varied. Probably most useful for setting variances to zero. |
| <code>optim.control</code> | List of control parameters for <a href="#">optim</a> . Method "L-BFGS-B" is used.                                                                                                                    |

## Details

*Structural time series* models are (linear Gaussian) state-space models for (univariate) time series based on a decomposition of the series into a number of components. They are specified by a set of error variances, some of which may be zero.

The simplest model is the *local level* model specified by `type = "level"`. This has an underlying level  $\mu_t$  which evolves by

$$\mu_{t+1} = \mu_t + \xi_t, \quad \xi_t \sim N(0, \sigma_\xi^2)$$

The observations are

$$x_t = \mu_t + \epsilon_t, \quad \epsilon_t \sim N(0, \sigma_\epsilon^2)$$

There are two parameters,  $\sigma_\xi^2$  and  $\sigma_\epsilon^2$ . It is an ARIMA(0,1,1) model, but with restrictions on the parameter set.

The *local linear trend model*, `type = "trend"`, has the same measurement equation, but with a time-varying slope in the dynamics for  $\mu_t$ , given by

$$\mu_{t+1} = \mu_t + \nu_t + \xi_t, \quad \xi_t \sim N(0, \sigma_\xi^2)$$

$$\nu_{t+1} = \nu_t + \zeta_t, \quad \zeta_t \sim N(0, \sigma_\zeta^2)$$

with three variance parameters. It is not uncommon to find  $\sigma_\zeta^2 = 0$  (which reduces to the local level model) or  $\sigma_\xi^2 = 0$ , which ensures a smooth trend. This is a restricted ARIMA(0,2,2) model.

The *basic structural model*, `type = "BSM"`, is a local trend model with an additional seasonal component. Thus the measurement equation is

$$x_t = \mu_t + \gamma_t + \epsilon_t, \quad \epsilon_t \sim N(0, \sigma_\epsilon^2)$$

where  $\gamma_t$  is a seasonal component with dynamics

$$\gamma_{t+1} = -\gamma_t + \dots + \gamma_{t-s+2} + \omega_t, \quad \omega_t \sim N(0, \sigma_\omega^2)$$

The boundary case  $\sigma_\omega^2 = 0$  corresponds to a deterministic (but arbitrary) seasonal pattern. (This is sometimes known as the ‘dummy variable’ version of the BSM.)

## Value

A list of class "StructTS" with components:

|               |                                                                                                                                                                                                                                   |
|---------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| coef          | the estimated variances of the components.                                                                                                                                                                                        |
| loglik        | the maximized log-likelihood. Note that as all these models are non-stationary this includes a diffuse prior for some observations and hence is not comparable to <a href="#">arima</a> nor different types of structural models. |
| loglik0       | the maximized log-likelihood with the constant used prior to R 3.0.0, for backwards compatibility.                                                                                                                                |
| data          | the time series x.                                                                                                                                                                                                                |
| residuals     | the standardized residuals.                                                                                                                                                                                                       |
| fitted        | a multiple time series with one component for the level, slope and seasonal components, estimated contemporaneously (that is at time $t$ and not at the end of the series).                                                       |
| call          | the matched call.                                                                                                                                                                                                                 |
| series        | the name of the series x.                                                                                                                                                                                                         |
| code          | the convergence code returned by <a href="#">optim</a> .                                                                                                                                                                          |
| model, model0 | Lists representing the Kalman filter used in the fitting. See <a href="#">KalmanLike</a> . model0 is the initial state of the filter, model its final state.                                                                      |
| xtsp          | the tsp attributes of x.                                                                                                                                                                                                          |

## Note

Optimization of structural models is a lot harder than many of the references admit. For example, the [AirPassengers](#) data are considered in Brockwell & Davis (1996): their solution appears to be a local maximum, but nowhere near as good a fit as that produced by StructTS. It is quite common to find fits with one or more variances zero, and this can include  $\sigma_\epsilon^2$ .

|-------------|------------------------------------------------|
| summary.aov | <i>Summarize an Analysis of Variance Model</i> |
|-------------|------------------------------------------------|

---

Description

Summarize an analysis of variance model.

Usage

```
## S3 method for class 'aov'
summary(object, intercept = FALSE, split,
        expand.split = TRUE, keep.zero.df = TRUE, ...)

## S3 method for class 'aovlist'
summary(object, ...)
```

Arguments

|              |                                                                                                                                                                                        |
|--------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| object       | An object of class "aov" or "aovlist".                                                                                                                                                 |
| intercept    | logical: should intercept terms be included?                                                                                                                                           |
| split        | an optional named list, with names corresponding to terms in the model. Each component is itself a list with integer components giving contrasts whose contributions are to be summed. |
| expand.split | logical: should the split apply also to interactions involving the factor?                                                                                                             |
| keep.zero.df | logical: should terms with no degrees of freedom be included?                                                                                                                          |
| ...          | Arguments to be passed to or from other methods, for summary.aovlist including those for summary.aov.                                                                                  |

**Value**

An object of class `c("summary.aov", "listof")` or `"summary.aovlist"` respectively.

For fits with a single stratum the result will be a list of ANOVA tables, one for each response (even if there is only one response): the tables are of class `"anova"` inheriting from class `"data.frame"`. They have columns `"Df"`, `"Sum Sq"`, `"Mean Sq"`, as well as `"F value"` and `"Pr(>F)"` if there are non-zero residual degrees of freedom. There is a row for each term in the model, plus one for `"Residuals"` if there are any.

For multistratum fits the return value is a list of such summaries, one for each stratum.

**Note**

The use of `expand.split = TRUE` is little tested: it is always possible to set it to `FALSE` and specify exactly all the splits required.

**See Also**

**Examples**

```
## For a simple example see example(aov)

# Cochran and Cox (1957, p.164)
# 3x3 factorial with ordered factors, each is average of 12.
CC <- data.frame(
  y = c(449, 413, 326, 409, 358, 291, 341, 278, 312)/12,
  P = ordered(gl(3, 3)), N = ordered(gl(3, 1, 9))
)
CC.aov <- aov(y ~ N * P, data = CC, weights = rep(12, 9))
summary(CC.aov)

# Split both main effects into linear and quadratic parts.
summary(CC.aov, split = list(N = list(L = 1, Q = 2),
                              P = list(L = 1, Q = 2)))

# Split only the interaction
summary(CC.aov, split = list("N:P" = list(L.L = 1, Q = 2:4)))

# split on just one var
summary(CC.aov, split = list(P = list(lin = 1, quad = 2)))
summary(CC.aov, split = list(P = list(lin = 1, quad = 2)),
        expand.split = FALSE)
```

**Description**

These functions are all [methods](#) for class `glm` or `summary.glm` objects.

**Usage**

```
## S3 method for class 'glm'
summary(object, dispersion = NULL, correlation = FALSE,
        symbolic.cor = FALSE, ...)

## S3 method for class 'summary.glm'
print(x, digits = max(3, getOption("digits") - 3),
      symbolic.cor = x$symbolic.cor,
      signif.stars = getOption("show.signif.stars"),
      show.residuals = FALSE, ...)
```

**Arguments**

|                             |                                                                                                                                                       |
|-----------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>object</code>         | an object of class "glm", usually, a result of a call to <a href="#">glm</a> .                                                                        |
| <code>x</code>              | an object of class "summary.glm", usually, a result of a call to <code>summary.glm</code> .                                                           |
| <code>dispersion</code>     | the dispersion parameter for the family used. Either a single numerical value or NULL (the default), when it is inferred from object (see 'Details'). |
| <code>correlation</code>    | logical; if TRUE, the correlation matrix of the estimated parameters is returned and printed.                                                         |
| <code>digits</code>         | the number of significant digits to use when printing.                                                                                                |
| <code>symbolic.cor</code>   | logical. If TRUE, print the correlations in a symbolic form (see <a href="#">symnum</a> ) rather than as numbers.                                     |
| <code>signif.stars</code>   | logical. If TRUE, 'significance stars' are printed for each coefficient.                                                                              |
| <code>show.residuals</code> | logical. If TRUE then a summary of the deviance residuals is printed at the head of the output.                                                       |
| <code>...</code>            | further arguments passed to or from other methods.                                                                                                    |

**Details**

`print.summary.glm` tries to be smart about formatting the coefficients, standard errors, etc. and additionally gives 'significance stars' if `signif.stars` is TRUE. The coefficients component of the result gives the estimated coefficients and their estimated standard errors, together with their ratio. This third column is labelled *t ratio* if the dispersion is estimated, and *z ratio* if the dispersion is known (or fixed by the family). A fourth column gives the two-tailed p-value corresponding to the *t* or *z* ratio based on a Student *t* or Normal reference distribution. (It is possible that the dispersion is not known and there are no residual degrees of freedom from which to estimate it. In that case the estimate is NaN.)

Aliased coefficients are omitted in the returned object but restored by the `print` method.

Correlations are printed to two decimal places (or symbolically): to see the actual correlations print `summary(object)$correlation` directly.

The dispersion of a GLM is not used in the fitting process, but it is needed to find standard errors. If dispersion is not supplied or NULL, the dispersion is taken as 1 for the binomial and Poisson families, and otherwise estimated by the residual Chi-squared statistic (calculated from cases with non-zero weights) divided by the residual degrees of freedom.

`summary` can be used with Gaussian `glm` fits to handle the case of a linear regression with known error variance, something not handled by [summary.lm](#).

**Value**

summary.glm returns an object of class "summary.glm", a list with components

|                |                                                                                                                                          |
|----------------|------------------------------------------------------------------------------------------------------------------------------------------|
| call           | the component from object.                                                                                                               |
| family         | the component from object.                                                                                                               |
| deviance       | the component from object.                                                                                                               |
| contrasts      | the component from object.                                                                                                               |
| df.residual    | the component from object.                                                                                                               |
| null.deviance  | the component from object.                                                                                                               |
| df.null        | the component from object.                                                                                                               |
| deviance.resid | the deviance residuals: see <a href="#">residuals.glm</a> .                                                                              |
| coefficients   | the matrix of coefficients, standard errors, z-values and p-values. Aliased coefficients are omitted.                                    |
| aliased        | named logical vector showing if the original coefficients are aliased.                                                                   |
| dispersion     | either the supplied argument or the inferred/estimated dispersion if the former is NULL.                                                 |
| df             | a 3-vector of the rank of the model and the number of residual degrees of freedom, plus number of coefficients (including aliased ones). |
| cov.unscaled   | the unscaled (dispersion = 1) estimated covariance matrix of the estimated coefficients.                                                 |
| cov.scaled     | ditto, scaled by dispersion.                                                                                                             |
| correlation    | (only if correlation is true.) The estimated correlations of the estimated coefficients.                                                 |
| symbolic.cor   | (only if correlation is true.) The value of the argument symbolic.cor.                                                                   |

*Summarizing Linear Model Fits*

---

**Description**

summary method for class "lm".

**Usage**

```
## S3 method for class 'lm'
summary(object, correlation = FALSE, symbolic.cor = FALSE, ...)

## S3 method for class 'summary.lm'
print(x, digits = max(3, getOption("digits") - 3),
      symbolic.cor = x$symbolic.cor,
      signif.stars = getOption("show.signif.stars"), ...)
```

**Arguments**

|              |                                                                                                                |
|--------------|----------------------------------------------------------------------------------------------------------------|
| object       | an object of class "lm", usually, a result of a call to <code>lm</code> .                                      |
| x            | an object of class "summary.lm", usually, a result of a call to <code>summary.lm</code> .                      |
| correlation  | logical; if TRUE, the correlation matrix of the estimated parameters is returned and printed.                  |
| digits       | the number of significant digits to use when printing.                                                         |
| symbolic.cor | logical. If TRUE, print the correlations in a symbolic form (see <code>symnum</code> ) rather than as numbers. |
| signif.stars | logical. If TRUE, 'significance stars' are printed for each coefficient.                                       |
| ...          | further arguments passed to or from other methods.                                                             |

**Details**

`print.summary.lm` tries to be smart about formatting the coefficients, standard errors, etc. and additionally gives 'significance stars' if `signif.stars` is TRUE.

Aliased coefficients are omitted in the returned object but restored by the `print` method.

Correlations are printed to two decimal places (or symbolically): to see the actual correlations print `summary(object)$correlation` directly.

**Value**

The function `summary.lm` computes and returns a list of summary statistics of the fitted linear model given in `object`, using the components (list elements) "call" and "terms" from its argument, plus

|              |                                                                                                                                                                            |
|--------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| residuals    | the <i>weighted</i> residuals, the usual residuals rescaled by the square root of the weights specified in the call to <code>lm</code> .                                   |
| coefficients | a $p \times 4$ matrix with columns for the estimated coefficient, its standard error, t-statistic and corresponding (two-sided) p-value. Aliased coefficients are omitted. |
| aliased      | named logical vector showing if the original coefficients are aliased.                                                                                                     |
| sigma        | the square root of the estimated variance of the random error                                                                                                              |

$$\hat{\sigma}^2 = \frac{1}{n-p} \sum_i w_i R_i^2,$$

where  $R_i$  is the  $i$ -th residual, `residuals[i]`.

|            |                                                                                                                                                           |
|------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------|
| df         | degrees of freedom, a 3-vector $(p, n-p, p^*)$ , the first being the number of non-aliased coefficients, the last being the total number of coefficients. |
| fstatistic | (for models including non-intercept terms) a 3-vector with the value of the F-statistic with its numerator and denominator degrees of freedom.            |
| r.squared  | $R^2$ , the 'fraction of variance explained by the model',                                                                                                |

$$R^2 = 1 - \frac{\sum_i R_i^2}{\sum_i (y_i - y^*)^2},$$

where  $y^*$  is the mean of  $y_i$  if there is an intercept and zero otherwise.

|               |                                                                                                                                |
|---------------|--------------------------------------------------------------------------------------------------------------------------------|
| adj.r.squared | the above $R^2$ statistic ' <i>adjusted</i> ', penalizing for higher $p$ .                                                     |
| cov.unscaled  | a $p \times p$ matrix of (unscaled) covariances of the $\hat{\beta}_j, j = 1, \dots, p$ .                                      |
| correlation   | the correlation matrix corresponding to the above <code>cov.unscaled</code> , if <code>correlation = TRUE</code> is specified. |
| symbolic.cor  | (only if <code>correlation</code> is true.) The value of the argument <code>symbolic.cor</code> .                              |
| na.action     | from <code>object</code> , if present there.                                                                                   |

Description

A summary method for class "manova".

Usage

```
## S3 method for class 'manova'
summary(object,
        test = c("Pillai", "Wilks", "Hotelling-Lawley", "Roy"),
        intercept = FALSE, tol = 1e-7, ...)
```

Arguments

|           |                                                                                                     |
|-----------|-----------------------------------------------------------------------------------------------------|
| object    | An object of class "manova" or an aov object with multiple responses.                               |
| test      | The name of the test statistic to be used. Partial matching is used so the name can be abbreviated. |
| intercept | logical. If TRUE, the intercept term is included in the table.                                      |
| tol       | tolerance to be used in deciding if the residuals are rank-deficient: see <a href="#">qr</a> .      |
| ...       | further arguments passed to or from other methods.                                                  |

Details

The `summary.manova` method uses a multivariate test statistic for the summary table. Wilks' statistic is most popular in the literature, but the default Pillai-Bartlett statistic is recommended by Hand and Taylor (1987).  
The table gives a transformation of the test statistic which has approximately an F distribution. The approximations used follow S-PLUS and SAS (the latter apart from some cases of the Hotelling-Lawley statistic), but many other distributional approximations exist: see Anderson (1984) and

Krzanowski and Marriott (1994) for further references. All four approximate F statistics are the same when the term being tested has one degree of freedom, but in other cases that for the Roy statistic is an upper bound.

The tolerance `tol` is applied to the QR decomposition of the residual correlation matrix (unless some response has essentially zero residuals, when it is unscaled). Thus the default value guards against very highly correlated responses: it can be reduced but doing so will allow rather inaccurate results and it will normally be better to transform the responses to remove the high correlation.

## Value

An object of class "summary.manova". If there is a positive residual degrees of freedom, this is a list with components

|                          |                                                                                   |
|--------------------------|-----------------------------------------------------------------------------------|
| <code>row.names</code>   | The names of the terms, the row names of the <code>stats</code> table if present. |
| <code>SS</code>          | A named list of sums of squares and product matrices.                             |
| <code>Eigenvalues</code> | A matrix of eigenvalues.                                                          |
| <code>stats</code>       | A matrix of the statistics, approximate F value, degrees of freedom and P value.  |

otherwise components `row.names`, `SS` and `Df` (degrees of freedom) for the terms (and not the residuals).

```

**Description**

summary method for class "nls".

**Usage**

```
## S3 method for class 'nls'
summary(object, correlation = FALSE, symbolic.cor = FALSE, ...)

## S3 method for class 'summary.nls'
print(x, digits = max(3, getOption("digits") - 3),
      symbolic.cor = x$symbolic.cor,
      signif.stars = getOption("show.signif.stars"), ...)
```

**Arguments**

|              |                                                                                                                   |
|--------------|-------------------------------------------------------------------------------------------------------------------|
| object       | an object of class "nls".                                                                                         |
| x            | an object of class "summary.nls", usually the result of a call to summary.nls.                                    |
| correlation  | logical; if TRUE, the correlation matrix of the estimated parameters is returned and printed.                     |
| digits       | the number of significant digits to use when printing.                                                            |
| symbolic.cor | logical. If TRUE, print the correlations in a symbolic form (see <a href="#">symnum</a> ) rather than as numbers. |
| signif.stars | logical. If TRUE, 'significance stars' are printed for each coefficient.                                          |
| ...          | further arguments passed to or from other methods.                                                                |

**Details**

The distribution theory used to find the distribution of the standard errors and of the residual standard error (for t ratios) is based on linearization and is approximate, maybe very approximate.

print.summary.nls tries to be smart about formatting the coefficients, standard errors, etc. and additionally gives 'significance stars' if signif.stars is TRUE.

Correlations are printed to two decimal places (or symbolically): to see the actual correlations print summary(object)\$correlation directly.

**Value**

The function summary.nls computes and returns a list of summary statistics of the fitted model given in object, using the component "formula" from its argument, plus

|              |                                                                                                                                          |
|--------------|------------------------------------------------------------------------------------------------------------------------------------------|
| residuals    | the <i>weighted</i> residuals, the usual residuals rescaled by the square root of the weights specified in the call to nls.              |
| coefficients | a $p \times 4$ matrix with columns for the estimated coefficient, its standard error, t-statistic and corresponding (two-sided) p-value. |

sigma the square root of the estimated variance of the random error

$$\hat{\sigma}^2 = \frac{1}{n-p} \sum_i R_i^2,$$

where  $R_i$  is the  $i$ -th weighted residual.

df degrees of freedom, a 2-vector  $(p, n-p)$ . (Here and elsewhere  $n$  omits observations with zero weights.)

cov.unscaled a  $p \times p$  matrix of (unscaled) covariances of the parameter estimates.

correlation the correlation matrix corresponding to the above cov.unscaled, if correlation = TRUE is specified and there are a non-zero number of residual degrees of freedom.

symbolic.cor (only if correlation is true.) The value of the argument symbolic.cor.

summary.princomp

*Summary method for Principal Components Analysis*

---

### Description

The [summary](#) method for class "princomp".

### Usage

```
## S3 method for class 'princomp'
summary(object, loadings = FALSE, cutoff = 0.1, ...)

## S3 method for class 'summary.princomp'
print(x, digits = 3, loadings = x$print.loadings,
      cutoff = x$cutoff, ...)
```

### Arguments

object an object of class "princomp", as from princomp().

loadings logical. Should loadings be included?

cutoff numeric. Loadings below this cutoff in absolute value are shown as blank in the output.

x an object of class "summary.princomp".

digits the number of significant digits to be used in listing loadings.

... arguments to be passed to or from other methods.

### Value

object with additional components cutoff and print.loadings.

|--------|---------------------------------|
| supsmu | <i>Friedman's SuperSmoother</i> |
|--------|---------------------------------|

---

Description

Smooth the (x, y) values by Friedman's 'super smoother'.

Usage

```
supsmu(x, y, wt =, span = "cv", periodic = FALSE, bass = 0, trace = FALSE)
```

Arguments

|          |                                                                                                                                       |
|----------|---------------------------------------------------------------------------------------------------------------------------------------|
| x        | x values for smoothing                                                                                                                |
| y        | y values for smoothing                                                                                                                |
| wt       | case weights, by default all equal                                                                                                    |
| span     | the fraction of the observations in the span of the running lines smoother, or "cv" to choose this by leave-one-out cross-validation. |
| periodic | if TRUE, the x values are assumed to be in [0, 1] and of period 1.                                                                    |
| bass     | controls the smoothness of the fitted curve. Values of up to 10 indicate increasing smoothness.                                       |
| trace    | logical, if true, prints one line of info "per spar", notably useful for "cv".                                                        |

Details

supsmu is a running lines smoother which chooses between three spans for the lines. The running lines smoothers are symmetric, with  $k/2$  data points each side of the predicted point, and values of  $k$  as  $0.5 * n$ ,  $0.2 * n$  and  $0.05 * n$ , where  $n$  is the number of data points. If span is specified, a single smoother with span  $span * n$  is used.

The best of the three smoothers is chosen by cross-validation for each prediction. The best spans are then smoothed by a running lines smoother and the final prediction chosen by linear interpolation.

The FORTRAN code says: "For small samples ( $n < 40$ ) or if there are substantial serial correlations between observations close in x-value, then a pre-specified fixed span smoother ( $span > 0$ ) should be used. Reasonable span values are 0.2 to 0.4."

Cases with non-finite values of x, y or wt are dropped, with a warning.

**Value**

- A list with components
  - x the input values in increasing order with duplicates removed.
  - y the corresponding y values on the fitted curve.

       abbr.colnames = has.colnames,
       lower.triangular = corr && is.numeric(x) && is.matrix(x),
       diag.lower.tri = corr && !is.null(show.max))
```

**Arguments**

|                  |                                                                                                                                                                                                                                                                                                                                                                                                        |
|------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| x                | numeric or logical vector or array.                                                                                                                                                                                                                                                                                                                                                                    |
| cutpoints        | numeric vector whose values $\text{cutpoints}[j] = c_j$ ( <i>after</i> augmentation, see <code>corr</code> below) are used for intervals.                                                                                                                                                                                                                                                              |
| symbols          | character vector, one shorter than (the <i>augmented</i> , see <code>corr</code> below) cutpoints. $\text{symbols}[j] = s_j$ are used as ‘code’ for the (half open) interval $(c_j, c_{j+1}]$ .<br>When <code>numeric.x</code> is FALSE, i.e., by default when argument <code>x</code> is logical, the default is <code>c(".", " ")</code> (graphical 0 / 1 s).                                        |
| legend           | logical indicating if a “legend” attribute is desired.                                                                                                                                                                                                                                                                                                                                                 |
| na               | character or logical. How NAs are coded. If <code>na == FALSE</code> , NAs are coded invisibly, <i>including</i> the “legend” attribute below, which otherwise mentions NA coding.                                                                                                                                                                                                                     |
| eps              | absolute precision to be used at left and right boundary.                                                                                                                                                                                                                                                                                                                                              |
| numeric.x        | logical indicating if <code>x</code> should be treated as numbers, otherwise as logical.                                                                                                                                                                                                                                                                                                               |
| corr             | logical. If TRUE, <code>x</code> contains correlations. The cutpoints are augmented by 0 and 1 and <code>abs(x)</code> is coded.                                                                                                                                                                                                                                                                       |
| show.max         | if TRUE, or of mode character, the maximal cutpoint is coded especially.                                                                                                                                                                                                                                                                                                                               |
| show.min         | if TRUE, or of mode character, the minimal cutpoint is coded especially.                                                                                                                                                                                                                                                                                                                               |
| abbr.colnames    | logical, integer or NULL indicating how column names should be abbreviated (if they are); if NULL (or FALSE and <code>x</code> has no column names), the column names will all be empty, i.e., “”; otherwise if <code>abbr.colnames</code> is false, they are left unchanged. If TRUE or integer, existing column names will be abbreviated to <code>abbreviate(*, minlength = abbr.colnames)</code> . |
| lower.triangular | logical. If TRUE and <code>x</code> is a matrix, only the <i>lower triangular</i> part of the matrix is coded as non-blank.                                                                                                                                                                                                                                                                            |
| diag.lower.tri   | logical. If <code>lower.triangular</code> <i>and</i> this are TRUE, the <i>diagonal</i> part of the matrix is shown.                                                                                                                                                                                                                                                                                   |

**Value**

An atomic character object of class `noquote` and the same dimensions as `x`.

If `legend` is TRUE (as by default when there are more than two classes), the result has an attribute “legend” containing a legend of the returned character codes, in the form

$$c_1 s_1 c_2 s_2 \dots s_n c_{n+1}$$

where  $c_j = \text{cutpoints}[j]$  and  $s_j = \text{symbols}[j]$ .

**Note**

The optional (mostly logical) arguments all try to use smart defaults. Specifying them explicitly may lead to considerably improved output in many cases.

## Examples

```
ii <- setNames(0:8, 0:8)
symnum(ii, cutpoints = 2*(0:4), symbols = c(".", "-", "+", "$"))
symnum(ii, cutpoints = 2*(0:4), symbols = c(".", "-", "+", "$"), show.max = TRUE)

symnum(1:12 %% 3 == 0) # --> "|" = TRUE, "." = FALSE for logical

## Pascal's Triangle modulo 2 -- odd and even numbers:
N <- 38
pascal <- t(sapply(0:N, function(n) round(choose(n, 0:N - (N-n)%/2))))
rownames(pascal) <- rep("", 1+N) # <-- to improve "graphic"
symnum(pascal %% 2, symbols = c(" ", "A"), numeric.x = FALSE)

##-- Symbolic correlation matrices:
symnum(cor(attitude), diag.lower.tri = FALSE)
symnum(cor(attitude), abbr.colnames = NULL)
symnum(cor(attitude), abbr.colnames = FALSE)
symnum(cor(attitude), abbr.colnames = 2)

symnum(cor(rbind(1, rnorm(25), rnorm(25)^2)))
symnum(cor(matrix(rexp(30, 1), 5, 18))) # <-- PATTERN ! --
symnum(cm1 <- cor(matrix(rnorm(90), 5, 18))) # < White Noise SMALL n
symnum(cm1, diag.lower.tri = FALSE)
symnum(cm2 <- cor(matrix(rnorm(900), 50, 18))) # < White Noise "BIG" n
symnum(cm2, lower.triangular = FALSE)

## NA's:
Cm <- cor(matrix(rnorm(60), 10, 6)); Cm[c(3,6), 2] <- NA
symnum(Cm, show.max = NULL)

## Graphical P-values (aka "significance stars"):
pval <- rev(sort(c(outer(1:6, 10^-(1:3)))))
symp <- symnum(pval, corr = FALSE,
               cutpoints = c(0, .001, .01, .05, .1, 1),
               symbols = c("***", "**", "*", ".", " "))
noquote(cbind(P.val = format(pval), Signif = symp))
```

---

t.test

*Student's t-Test*

---

## Description

Performs one and two sample t-tests on vectors of data.

## Usage

```
t.test(x, ...)

## Default S3 method:
t.test(x, y = NULL,
       alternative = c("two.sided", "less", "greater"),
       mu = 0, paired = FALSE, var.equal = FALSE,
       conf.level = 0.95, ...)
```

```
## S3 method for class 'formula'
t.test(formula, data, subset, na.action = na.pass, ...)
```

### Arguments

|             |                                                                                                                                                                                                                                                                                   |
|-------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| x           | a (non-empty) numeric vector of data values.                                                                                                                                                                                                                                      |
| y           | an optional (non-empty) numeric vector of data values.                                                                                                                                                                                                                            |
| alternative | a character string specifying the alternative hypothesis, must be one of "two.sided" (default), "greater" or "less". You can specify just the initial letter.                                                                                                                     |
| mu          | a number indicating the true value of the mean (or difference in means if you are performing a two sample test).                                                                                                                                                                  |
| paired      | a logical indicating whether you want a paired t-test.                                                                                                                                                                                                                            |
| var.equal   | a logical variable indicating whether to treat the two variances as being equal. If TRUE then the pooled variance is used to estimate the variance otherwise the Welch (or Satterthwaite) approximation to the degrees of freedom is used.                                        |
| conf.level  | confidence level of the interval.                                                                                                                                                                                                                                                 |
| formula     | a formula of the form lhs ~ rhs where lhs is a numeric variable giving the data values and rhs either 1 for a one-sample or paired test or a factor with two levels giving the corresponding groups. If lhs is of class "Pair" and rhs is 1, a paired test is done, see Examples. |
| data        | an optional matrix or data frame (or similar: see <a href="#">model.frame</a> ) containing the variables in the formula formula. By default the variables are taken from environment(formula).                                                                                    |
| subset      | an optional vector specifying a subset of observations to be used.                                                                                                                                                                                                                |
| na.action   | a function which indicates what should happen when the data contain NAs.                                                                                                                                                                                                          |
| ...         | further arguments to be passed to or from methods. For the formula method, this includes arguments of the default method, but not paired.                                                                                                                                         |

### Details

alternative = "greater" is the alternative that x has a larger mean than y. For the one-sample case: that the mean is positive.

If paired is TRUE then both x and y must be specified and they must be the same length. Missing values are silently removed (in pairs if paired is TRUE). If var.equal is TRUE then the pooled estimate of the variance is used. By default, if var.equal is FALSE then the variance is estimated separately for both groups and the Welch modification to the degrees of freedom is used.

If the input data are effectively constant (compared to the larger of the two means) an error is generated.

If the data contain infinite values, t.test() no longer errors and returns a still not very useful result. Note that [wilcox.test\(\)](#) is *robust* against outliers and hence deals more usefully with such Inf values in x or y.

### Value

A list with class "htest" containing the following components:

|           |                               |
|-----------|-------------------------------|
| statistic | the value of the t-statistic. |
|-----------|-------------------------------|

|             |                                                                                                                                     |
|-------------|-------------------------------------------------------------------------------------------------------------------------------------|
| parameter   | the degrees of freedom for the t-statistic.                                                                                         |
| p.value     | the p-value for the test.                                                                                                           |
| conf.int    | a confidence interval for the mean appropriate to the specified alternative hypothesis.                                             |
| estimate    | the estimated mean or difference in means depending on whether it was a one-sample test or a two-sample test.                       |
| null.value  | the specified hypothesized value of the mean or mean difference depending on whether it was a one-sample test or a two-sample test. |
| stderr      | the standard error of the mean (difference), used as denominator in the t-statistic formula.                                        |
| alternative | a character string describing the alternative hypothesis.                                                                           |
| method      | a character string indicating what type of t-test was performed.                                                                    |
| data.name   | a character string giving the name(s) of the data.                                                                                  |

### Examples

```
## Two-sample t-test
t.test(1:10, y = c(7:20))      # P = .00001855
t.test(1:10, y = c(7:20, 200)) # P = .1245    -- NOT significant anymore

## Traditional interface
with(mtcars, t.test(mpg[am == 0], mpg[am == 1]))

## Formula interface
t.test(mpg ~ am, data = mtcars)

## One-sample t-test
## Traditional interface
t.test(sleep$extra)

## Formula interface
t.test(extra ~ 1, data = sleep)

## Paired t-test
## The sleep data is actually paired, so could have been in wide format:
sleep2 <- reshape(sleep, direction = "wide",
                  idvar = "ID", timevar = "group")

## Traditional interface
t.test(sleep2$extra.1, sleep2$extra.2, paired = TRUE)

## Formula interface
t.test(Pair(extra.1, extra.2) ~ 1, data = sleep2)
```

## Description

Density, distribution function, quantile function and random generation for the *t* distribution with *df* degrees of freedom (and optional non-centrality parameter *ncp*).

## Usage

```
dt(x, df, ncp, log = FALSE)
pt(q, df, ncp, lower.tail = TRUE, log.p = FALSE)
qt(p, df, ncp, lower.tail = TRUE, log.p = FALSE)
rt(n, df, ncp)
```

## Arguments

|                                       |                                                                                                                                                                                       |
|---------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>x</i> , <i>q</i>                   | vector of quantiles.                                                                                                                                                                  |
| <i>p</i>                              | vector of probabilities.                                                                                                                                                              |
| <i>n</i>                              | number of observations. If <code>length(n) &gt; 1</code> , the length is taken to be the number required.                                                                             |
| <i>df</i>                             | degrees of freedom ( $> 0$ , maybe non-integer). <code>df = Inf</code> is allowed.                                                                                                    |
| <i>ncp</i>                            | non-centrality parameter $\delta$ ; currently except for <code>rt()</code> , accurate only for <code>abs(ncp) &lt;= 37.62</code> . If omitted, use the central <i>t</i> distribution. |
| <code>log</code> , <code>log.p</code> | logical; if TRUE, probabilities <i>p</i> are given as <code>log(p)</code> .                                                                                                           |
| <code>lower.tail</code>               | logical; if TRUE (default), probabilities are $P[X \leq x]$ , otherwise, $P[X > x]$ .                                                                                                 |

## Details

The *t* distribution with *df* =  $\nu$  degrees of freedom has density

$$f(x) = \frac{\Gamma((\nu + 1)/2)}{\sqrt{\pi\nu}\Gamma(\nu/2)}(1 + x^2/\nu)^{-(\nu+1)/2}$$

for all real *x*. It has mean 0 (for  $\nu > 1$ ) and variance  $\frac{\nu}{\nu-2}$  (for  $\nu > 2$ ).

The general *non-central t* with parameters  $(\nu, \delta) = (\text{df}, \text{ncp})$  is defined as the distribution of  $T_\nu(\delta) := (U + \delta)/\sqrt{V/\nu}$  where *U* and *V* are independent random variables,  $U \sim \mathcal{N}(0, 1)$  and  $V \sim \chi_\nu^2$  (see [Chisquare](#)).

The most used applications are power calculations for *t*-tests:

Let  $T = \frac{\bar{X} - \mu_0}{S/\sqrt{n}}$  where  $\bar{X}$  is the [mean](#) and *S* the sample standard deviation ([sd](#)) of  $X_1, X_2, \dots, X_n$  which are i.i.d.  $\mathcal{N}(\mu, \sigma^2)$  Then *T* is distributed as non-central *t* with *df* =  $n - 1$  degrees of freedom and non-centrality parameter  $\text{ncp} = (\mu - \mu_0)\sqrt{n}/\sigma$ .

The *t* distribution's cumulative distribution function (cdf),  $F_\nu$  fulfills  $F_\nu(t) = \frac{1}{2}I_x(\frac{\nu}{2}, \frac{1}{2})$ , for  $t \leq 0$ , and  $F_\nu(t) = 1 - \frac{1}{2}I_x(\frac{\nu}{2}, \frac{1}{2})$ , for  $t \geq 0$ , where  $x := \nu/(\nu + t^2)$ , and  $I_x(a, b)$  is the incomplete beta function, in R this is [pbeta](#)(*x*, *a*, *b*).

**Value**

dt gives the density, pt gives the distribution function, qt gives the quantile function, and rt generates random deviates.

Invalid arguments will result in return value NaN, with a warning.

The length of the result is determined by n for rt, and is the maximum of the lengths of the numerical arguments for the other functions.

The numerical arguments other than n are recycled to the length of the result. Only the first elements of the logical arguments are used.

**Note**

Supplying  $ncp = 0$  uses the algorithm for the non-central distribution, which is not the same algorithm used if ncp is omitted. This is to give consistent behaviour in extreme cases with values of ncp very near zero.

The code for non-zero ncp is principally intended to be used for moderate values of ncp: it will not be highly accurate, especially in the tails, for large values.

**Source**

The central dt is computed via an accurate formula provided by Catherine Loader (see the reference in [dbinom](#)).

For the non-central case of dt, C code contributed by Claus Ekstrøm based on the relationship (for  $x \neq 0$ ) to the cumulative distribution.

For the central case of pt, a normal approximation in the tails, otherwise via [pbeta](#).

For the non-central case of pt based on a C translation of

Lenth, R. V. (1989). *Algorithm AS 243* — Cumulative distribution function of the non-central  $t$  distribution, *Applied Statistics* **38**, 185–189; doi:[10.2307/2347693](#) .

This computes the lower tail only, so the upper tail currently suffers from cancellation and a warning will be given when this is likely to be significant.

For central qt, a C translation of

Hill, G. W. (1970) Algorithm 396: Student's  $t$ -quantiles. *Communications of the ACM*, **13**(10), 619–620; doi:[10.1145/355598.355599](#) .

altered to take account of

Hill, G. W. (1981) Remark on Algorithm 396, *ACM Transactions on Mathematical Software*, **7**, 250–1; doi:[10.1145/355945.355956](#) .

The non-central case is done by inversion.

termplot

---

*Plot Regression Terms*

---

## Description

Plots regression terms against their predictors, optionally with standard errors and partial residuals added.

## Usage

```
termplot(model, data = NULL, envir = environment(formula(model)),
  partial.resid = FALSE, rug = FALSE,
  terms = NULL, se = FALSE,
  xlabs = NULL, ylabs = NULL, main = NULL,
  col.term = 2, lwd.term = 1.5,
  col.se = "orange", lty.se = 2, lwd.se = 1,
  col.res = "gray", cex = 1, pch = par("pch"),
  col.smth = "darkred", lty.smth = 2, span.smth = 2/3,
  ask = dev.interactive() && nb.fig < n.tms,
  use.factor.levels = TRUE, smooth = NULL, ylim = "common",
  plot = TRUE, transform.x = FALSE, ...)
```

## Arguments

|                                            |                                                                                                                                                                                                                                                                                                                                    |
|--------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>model</code>                         | fitted model object                                                                                                                                                                                                                                                                                                                |
| <code>data</code>                          | data frame in which variables in <code>model</code> can be found                                                                                                                                                                                                                                                                   |
| <code>envir</code>                         | environment in which variables in <code>model</code> can be found                                                                                                                                                                                                                                                                  |
| <code>partial.resid</code>                 | logical; should partial residuals be plotted?                                                                                                                                                                                                                                                                                      |
| <code>rug</code>                           | add <a href="#">rugplots</a> (jittered 1-d histograms) to the axes?                                                                                                                                                                                                                                                                |
| <code>terms</code>                         | which terms to plot (default <code>NULL</code> means all terms); a vector passed to <a href="#">predict</a> ( <code>..</code> , <code>type = "terms"</code> , <code>terms = *</code> ).                                                                                                                                            |
| <code>se</code>                            | plot pointwise standard errors?                                                                                                                                                                                                                                                                                                    |
| <code>xlabs</code>                         | vector of labels for the x axes                                                                                                                                                                                                                                                                                                    |
| <code>ylabs</code>                         | vector of labels for the y axes                                                                                                                                                                                                                                                                                                    |
| <code>main</code>                          | logical, or vector of main titles; if <code>TRUE</code> , the model's call is taken as main title, <code>NULL</code> or <code>FALSE</code> mean no titles.                                                                                                                                                                         |
| <code>col.term, lwd.term</code>            | color and line width for the 'term curve', see <a href="#">lines</a> .                                                                                                                                                                                                                                                             |
| <code>col.se, lty.se, lwd.se</code>        | color, line type and line width for the 'twice-standard-error curve' when <code>se = TRUE</code> .                                                                                                                                                                                                                                 |
| <code>col.res, cex, pch</code>             | color, plotting character expansion and type for partial residuals, when <code>partial.resid = TRUE</code> , see <a href="#">points</a> .                                                                                                                                                                                          |
| <code>ask</code>                           | logical; if <code>TRUE</code> , the user is <i>asked</i> before each plot, see <a href="#">par</a> ( <code>ask=.</code> ).                                                                                                                                                                                                         |
| <code>use.factor.levels</code>             | Should x-axis ticks use factor levels or numbers for factor terms?                                                                                                                                                                                                                                                                 |
| <code>smooth</code>                        | <code>NULL</code> or a function with the same arguments as <a href="#">panel.smooth</a> to draw a smooth through the partial residuals for non-factor terms                                                                                                                                                                        |
| <code>lty.smth, col.smth, span.smth</code> | Passed to <code>smooth</code>                                                                                                                                                                                                                                                                                                      |
| <code>ylim</code>                          | an optional range for the y axis, or "common" when a range sufficient for all the plot will be computed, or "free" when limits are computed for each plot.                                                                                                                                                                         |
| <code>plot</code>                          | if set to <code>FALSE</code> plots are not produced: instead a list is returned containing the data that would have been plotted.                                                                                                                                                                                                  |
| <code>transform.x</code>                   | logical vector; if an element (recycled as necessary) is <code>TRUE</code> , partial residuals for the corresponding term are plotted against transformed values. The model response is then a straight line, allowing a ready comparison against the data or against the curve obtained from <code>smooth = panel.smooth</code> . |
| <code>...</code>                           | other graphical parameters.                                                                                                                                                                                                                                                                                                        |

## Details

The `model` object must have a `predict` method that accepts `type = "terms"`, e.g., [glm](#) in the **stats** package, [coxph](#) and [survreg](#) in the **survival** package.

For the `partial.resid = TRUE` option `model` must have a [residuals](#) method that accepts `type = "partial"`, which [lm](#) and [glm](#) do.

The `data` argument should rarely be needed, but in some cases `termplot` may be unable to reconstruct the original data frame. Using `na.action=na.exclude` makes these problems less likely.

Nothing sensible happens for interaction terms, and they may cause errors.

The `plot = FALSE` option is useful when some special action is needed, e.g. to overlay the results of two different models or to plot confidence bands.

**Value**

For `plot = FALSE`, a list with one element for each plot which would have been produced. Each element of the list is a data frame with variables `x`, `y`, and optionally the pointwise standard errors `se`. For continuous predictors `x` will contain the ordered unique values and for a factor it will be a factor containing one instance of each level. The list has attribute `"constant"` copied from the predicted terms object.

Otherwise, the number of terms, invisibly.

**See Also**

For (generalized) linear models, [plot.lm](#) and [predict.glm](#).

**Examples**

```
require(graphics)

had.splines <- "package:splines" %in% search()
if(!had.splines) rs <- require(splines)
x <- 1:100
z <- factor(rep(LETTERS[1:4], 25))
y <- rnorm(100, sin(x/10)+as.numeric(z))
model <- glm(y ~ ns(x, 6) + z)

par(mfrow = c(2,2)) ## 2 x 2 plots for same model :
termplot(model, main = paste("termplot( ", deparse(model$call), " ...)") )
termplot(model, rug = TRUE)
termplot(model, partial.resid = TRUE, se = TRUE, main = TRUE)
termplot(model, partial.resid = TRUE, smooth = panel.smooth, span.smth = 1/4)
if(!had.splines && rs) detach("package:splines")

if(requireNamespace("MASS", quietly = TRUE)) {
  hills.lm <- lm(log(time) ~ log(climb)+log(dist), data = MASS::hills)
  termplot(hills.lm, partial.resid = TRUE, smooth = panel.smooth,
           terms = "log(dist)", main = "Original")
  termplot(hills.lm, transform.x = TRUE,
           partial.resid = TRUE, smooth = panel.smooth,
           terms = "log(dist)", main = "Transformed")
}
```

---

terms

---

*Model Terms*

---

**Description**

The function `terms` is a generic function which can be used to extract *terms* objects from various kinds of R data objects.

**Usage**

```
terms(x, ...)
```

**Arguments**

`x` object used to select a method to dispatch.  
`...` further arguments passed to or from other methods.

**Details**

There are methods for classes "aovlist", "terms", and "formula" (see [terms.formula](#)): the default method just extracts the `terms` component of the object, or failing that a "terms" attribute (as used by [model.frame](#)).

There are [print](#) and [labels](#) methods for class "terms": the latter extracts the term labels (see [?terms.object](#)).

**Value**

An object of class `c("terms", "formula")` which contains the *terms* representation of a symbolic model. See [?terms.object](#) for its structure.

**References**

Chambers, J. M. and Hastie, T. J. (1992) *Statistical models*. Chapter 2 of *Statistical Models in S* eds J. M. Chambers and T. J. Hastie, Wadsworth & Brooks/Cole.

**See Also**

---

`terms.formula`

*Construct a terms Object from a Formula*

---

**Description**

This function takes a formula and some optional arguments and constructs a [terms](#) object, which can then be used to construct a [model.matrix](#).

**Usage**

```
## S3 method for class 'formula'
terms(x, specials = NULL, abb = NULL, data = NULL, neg.out = TRUE,
      keep.order = FALSE, simplify = FALSE, ...,
      allowDotAsName = FALSE)
```

**Arguments**

`x` a [formula](#).  
`specials` an optional character vector listing names of functions. Calls to these functions in the formula are marked as special in the terms object.  
`abb` Not implemented in R; deprecated.  
`data` a data frame from which the meaning of the special symbol `.` can be inferred. It is used only if there is a `.` in the formula.  
`neg.out` Not implemented in R; deprecated.

- keep.order      a logical value indicating whether the terms should keep their positions. By default, when FALSE, the terms are reordered so that main effects come first, followed by the interactions, all second-order, all third-order and so on. Effects of a given order are kept in the order specified.
- simplify        should the formula be expanded and simplified, the pre-1.7.0 behaviour?
- ...              further arguments passed to or from other methods.
- allowDotAsName normally . in a formula refers to the remaining variables contained in data. Exceptionally, . can be treated as a name for non-standard uses of formulae.

Details

Non-syntactic specials are supported since R 4.6.0. specials="pkg::name" marks as special calls ``pkg::name`(...)` (note backticks) and *not* calls `pkg::name(...)`. The reverse was true prior to R 4.6.0, but that was undocumented and accidental.

Value

A terms object is returned. It is the re-ordered formula (unless keep.order = TRUE) with several [attributes](#), see [terms.object](#) for details. In all cases variables within an interaction term in the formula are re-ordered by the ordering of the "variables" attribute, which is the order in which the variables occur in the formula.

See Also

[terms](#), [terms.object](#), also for examples.

|--------------|-------------------------------------|
| terms.object | <i>Description of Terms Objects</i> |
|--------------|-------------------------------------|

---

Description

An object of class [terms](#) holds information about a model. Usually the model was specified in terms of a [formula](#) and that formula was used to determine the terms object.

Details

The object itself is simply the result of `terms.formula(<formula>)`. It has a number of attributes and they are used to construct the model frame:

- factors    An integer matrix of variables by terms showing which variables appear in which terms. The entries are
- 0    if the variable does not occur in the term,
  - 1    if it does occur and should be coded by contrasts, and
  - 2    if it occurs and should be coded via dummy variables for all levels (as when a lower-order term is missing).

Note that variables in main effects always receive 1, even if the intercept is missing (in which case the first one should be coded with dummy variables). If there are no terms other than an intercept and offsets, this is `integer(0)`.

**term.labels** A character vector containing the labels for each of the terms in the model, except for offsets. Note that these are after possible re-ordering of terms.

Non-syntactic names will be quoted by backticks: this makes it easier to re-construct the formula from the term labels.

**variables** A call to `list` of the variables in the model.

**intercept** Either 0, indicating no intercept is to be fit, or 1 indicating that an intercept is to be fit.

**order** A vector of the same length as `term.labels` indicating the order of interaction for each term.

**response** The index of the variable (in `variables`) of the response (the left hand side of the formula). Zero, if there is no response.

**offset** If the model contains `offset` terms there is an `offset` attribute indicating which variables are offsets.

**specials** If a `specials` argument was given to `terms.formula` there is a `specials` attribute, a pairlist of vectors (one for each specified special function) giving numeric indices of the arguments of the list returned as the `variables` attribute which contain these special functions.

**dataClasses** optional. A named character vector giving the classes (as given by `.MFclass`) of the variables used in a fit.

**predvars** optional. An expression to help in computing predictions at new covariate values; see `makepredictcall`.

The object has class `c("terms", "formula")`.

## Note

These objects are different from those found in S. In particular there is no `formula` attribute: instead the object is itself a formula. (Thus, the mode of a `terms` object is different.)

Examples of the `specials` argument can be seen in the `aov` and `coxph` functions, the latter from package **survival**.

## See Also

`terms`, `formula`.

## Examples

```
## use of specials (as used for gam() in packages mgcv and gam)
(tf <- terms(y ~ x + x:z + s(x), specials = "s"))
## Note that the "factors" attribute has variables as row names
## and term labels as column names, both as character vectors.
attr(tf, "specials")    # index 's' variable(s)
rownames(attr(tf, "factors"))[attr(tf, "specials")$s]

## we can keep the order by
terms(y ~ x + x:z + s(x), specials = "s", keep.order = TRUE)

## use of '::' in terms to be marked as special is *wrong*
ff <- list(y ~      offset(w) + x1 +      s(x2),
           y ~ stats::offset(w) + x1 + mgcv::s(x2))
tt <- lapply(ff, terms, specials = c("s", "mgcv::s"))
lapply(tt, attr, "offset")
lapply(tt, attr, "specials")
```

time

*Sampling Times of Time Series***Description**

`time` creates the vector of times at which a time series was sampled.

`cycle` gives the positions in the cycle of each observation.

`frequency` returns the number of samples per unit time and `deltat` the time interval between observations (see [ts](#)).

**Usage**

```
time(x, ...)
## Default S3 method:
time(x, offset = 0, ts.eps = getOption("ts.eps"), ...)

cycle(x, ...)
frequency(x, ...)
deltat(x, ...)
```

**Arguments**

|                     |                                                                                                                                                                                                               |
|---------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>      | a univariate or multivariate time-series, or a vector or matrix.                                                                                                                                              |
| <code>offset</code> | can be used to indicate when sampling took place in the time unit. 0 (the default) indicates the start of the unit, 0.5 the middle and 1 the end of the interval.                                             |
| <code>ts.eps</code> | time series comparison tolerance, used in <code>time()</code> to determine if values close than <code>ts.eps</code> to an integer should be <a href="#">round</a> ()ed to it in order to preserve the “year”. |
| <code>...</code>    | extra arguments for future methods.                                                                                                                                                                           |

**Details**

These are all generic functions, which will use the [tsp](#) attribute of `x` if it exists. `time` and `cycle` have methods for class [ts](#) that coerce the result to that class.

`time()` [round](#)()s values close to an integer, i.e., closer than `ts.eps`, since R 4.3.0. For previous behaviour, you can call it with `ts.eps = 0`.

require(graphics)

cycle(presidents)
# a simple series plot
plot(as.vector(time(presidents)), as.vector(presidents), type = "l")
```

toeplitz

*Create Symmetric and Asymmetric Toeplitz Matrix***Description**

In its simplest use, `toeplitz()` forms a symmetric Toeplitz matrix given its first column (or row). For the general case, asymmetric and non-square Toeplitz matrices are formed either by specifying the first column and row separately,

```
T1 <- toeplitz(col, row)
```

or by

```
T <- toeplitz2(x, nr, nc)
```

where only one of  $(nr, nc)$  needs to be specified. In the latter case, the simple equivalence  $T_{i,j} = x_{i-j+n_c}$  is fulfilled where  $n_c = ncol(T)$ .

**Usage**

```
toeplitz(x, r = NULL, symmetric = is.null(r))
toeplitz2(x, nrow = length(x) + 1 - ncol, ncol = length(x) + 1 - nrow)
```

**Arguments**

|                         |                                                                                                                                                                                                                                                 |
|-------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>          | for <code>toeplitz(x, *)</code> : the first column of the Toeplitz matrix; for <code>toeplitz2(x, *)</code> it is the upper-and-left border of the Toeplitz matrix, i.e., from top-right to bottom-left, such that $T[i, j] == x[i-j + ncol]$ . |
| <code>r</code>          | the first row of the target Toeplitz matrix; only needed in asymmetric cases.                                                                                                                                                                   |
| <code>symmetric</code>  | optional <b>logical</b> indicating if the matrix should be symmetric.                                                                                                                                                                           |
| <code>nrow, ncol</code> | the number of rows and columns; only one needs to be specified.                                                                                                                                                                                 |

**Value**

The  $n \times m$  Toeplitz matrix  $T$ ; for

`toeplitz()`:  $\dim(T)$  is  $(n, m)$  and  $m == \text{length}(x)$  and  $n == m$  in the symmetric case or  $n == \text{length}(r)$  otherwise.

`toeplitz2()`:  $\dim(T) == c(nrow, ncol)$ .

**Author(s)**

A. Trapletti and Martin Maechler (speedup and asymmetric extensions)

## Examples

```
x <- 1:5
toeplitz(x)

T. <- toeplitz(1:5, 11:13) # with a *Warning* x[1] != r[1]
T2 <- toeplitz2(c(13:12, 1:5), 5, 3) # this is the same matrix:
stopifnot(identical(T., T2))

# Matrix of character (could also have logical, raw, complex ..) {also warning}:
noquote(toeplitz(letters[1:4], LETTERS[20:26]))

## A convolution/smoother weight matrix :
m <- 17
k <- length(wts <- c(76, 99, 60, 20, 1))
n <- m-k+1
## Convolution
W <- toeplitz2(c(rep(0, m-k), wts, rep(0, m-k)), ncol=n)

## "display" nicely :
if(requireNamespace("Matrix"))
  print(Matrix::Matrix(W)) else {
    colnames(W) <- paste0(",", if(n <= 9) 1:n else c(1:9, letters[seq_len(n-9)]))
    print(W)
  }

## scale W to have column sums 1:
W. <- W / sum(wts)
all.equal(rep(1, ncol(W.)), colSums(W.), check.attributes = FALSE)
## Visualize "mass-preserving" convolution
x <- 1:n; f <- function(x) exp(-((x - .4*n)/3)^2)
y <- f(x) + rep_len(3:-2, n)/10
## Smoothing convolution:
y.hat <- W. %*% y # y.hat := smoothed(y) ("mass preserving" -> longer than y)
stopifnot(length(y.hat) == m, m == n + (k-1))
plot(x,y, type="b", xlim=c(1,m)); curve(f(x), 1,n, col="gray", lty=2, add=TRUE)
lines(1:m, y.hat, col=2, lwd=3)
rbind(sum(y), sum(y.hat)) ## mass preserved

## And, yes, convolve(y, *) does the same when called appropriately:
all.equal(c(y.hat), convolve(y, rev(wts/sum(wts)), type="open"))
```

## Description

The function `ts` is used to create time-series objects.

`as.ts` and `is.ts` coerce an object to a time-series and test whether an object is a time series.

## Usage

```
ts(data = NA, start = 1, end = numeric(), frequency = 1,
    deltat = 1, ts.eps = getOption("ts.eps"),
```

```

      class = if(nseries > 1) c("mts", "ts", "matrix", "array") else "ts",
      names = )
as.ts(x, ...)
is.ts(x)

is.mts(x)

```

### Arguments

|                        |                                                                                                                                                                                                                                                                    |
|------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>data</code>      | a vector or matrix of the observed time-series values. A data frame will be coerced to a numeric matrix via <code>data.matrix</code> . (See also ‘Details’.)                                                                                                       |
| <code>start</code>     | the time of the first observation. Either a single number or a vector of two numbers (the second of which is an integer), which specify a natural time unit and a (1-based) number of samples into the time unit. See the examples for the use of the second form. |
| <code>end</code>       | the time of the last observation, specified in the same way as <code>start</code> .                                                                                                                                                                                |
| <code>frequency</code> | the number of observations per unit of time.                                                                                                                                                                                                                       |
| <code>deltat</code>    | the fraction of the sampling period between successive observations; e.g., 1/12 for monthly data. Only one of <code>frequency</code> or <code>deltat</code> should be provided.                                                                                    |
| <code>ts.eps</code>    | time series comparison tolerance. Frequencies are considered equal if their absolute difference is less than <code>ts.eps</code> . It is also used to check consistency of <code>end - start</code> , <code>frequency</code> , and the length of the time-series.  |
| <code>class</code>     | class to be given to the result, or none if NULL or "none". The default is "ts" for a single series, or <code>c("mts", "ts", "matrix", "array")</code> for multiple series.                                                                                        |
| <code>names</code>     | a character vector of names for the series in a multiple series: defaults to the <code>colnames</code> of <code>data</code> , or "Series 1", "Series 2", ....                                                                                                      |
| <code>x</code>         | an arbitrary R object.                                                                                                                                                                                                                                             |
| <code>...</code>       | arguments passed to methods (unused for the default method).                                                                                                                                                                                                       |

### Details

The function `ts` is used to create time-series objects. These are vectors or matrices which inherit from class "ts" (and have additional attributes) which represent data sampled at equispaced points in time. In the matrix case, each column of the matrix `data` is assumed to contain a single (univariate) time series. Time series must have at least one observation, and although they need not be numeric there is very limited support for non-numeric series.

Class "ts" has a number of methods. In particular arithmetic will attempt to align time axes, and subsetting to extract subsets of series can be used (e.g., `EuStockMarkets[, "DAX"]`). However, subsetting the first (or only) dimension will return a matrix or vector, as will matrix subsetting. Subassignment can be used to replace values but not to extend a series (see [window](#)). There is a method for `t` that transposes the series as a matrix (a one-column matrix if a vector) and hence returns a result that does not inherit from class "ts".

Argument `frequency` indicates the sampling frequency of the time series, with the default value 1 indicating one sample in each unit time interval. For example, one could use a value of 7 for frequency when the data are sampled daily, and the natural time period is a week, or 12 when the data are sampled monthly and the natural time period is a year. Values of 4 and 12 are assumed in (e.g.) print methods to imply a quarterly and monthly series respectively. `frequency` need not be a whole number: for example, `frequency = 0.2` would imply sampling once every five time units.

`as.ts` is generic. Its default method will use the `tsp` attribute of the object if it has one to set the start and end times and frequency.

`is.ts()` tests if an object is a time series, i.e., inherits from "ts" and is of positive length.

`is.mts(x)` tests if an object `x` is a multivariate time series, i.e., fulfills `is.ts(x)`, `is.matrix(x)` and inherits from class "mts".

`tsp`, `frequency`, `start`, `end`, `time`, `window`; `print.ts`, the print method for time series objects; `plot.ts`, the plot method for time series objects.

For other definitions of 'time series' (e.g., time-ordered observations) see the CRAN task view at <https://CRAN.R-project.org/view=TimeSeries>.

## Examples

```
require(graphics)

ts(1:10, frequency = 4, start = c(1959, 2)) # 2nd Quarter of 1959
print( ts(1:10, frequency = 7, start = c(12, 2)), calendar = TRUE)
# print.ts(.)
## Using July 1954 as start date:
gnp <- ts(cumsum(1 + round(rnorm(100), 2)),
          start = c(1954, 7), frequency = 12)
plot(gnp) # using 'plot.ts' for time-series plot

utils:: methods(class = "ts") # all functions with methods available for "ts"

## "ts" methods for head() and tail()
utils:: head(lynx, 4)
utils:: tail(lynx, -7)

## Multivariate
z <- ts(matrix(rnorm(300), 100, 3), start = c(1961, 1), frequency = 12)
class(z)
is.mts(z)
head(z) # "ts" method ==> incl. times:
plot(z)
plot(z, plot.type = "single", lty = 1:3)

## A phase plot:
plot(nhtemp, lag(nhtemp, 1), cex = .8, col = "blue",
     main = "Lag plot of New Haven temperatures")
```

## Description

Methods for objects of class "ts", typically the result of `ts`.

**Usage**

```
## S3 method for class 'ts'
diff(x, lag = 1, differences = 1, ...)

## S3 method for class 'ts'
na.omit(object, ...)
```

**Arguments**

|             |                                                                  |
|-------------|------------------------------------------------------------------|
| x           | an object of class "ts" containing the values to be differenced. |
| lag         | an integer indicating which lag to use.                          |
| differences | an integer indicating the order of the difference.               |
| object      | a univariate or multivariate time series.                        |
| ...         | further arguments to be passed to or from methods.               |

**Details**

The `na.omit` method omits initial and final segments with missing values in one or more of the series. 'Internal' missing values will lead to failure.

**Value**

For the `na.omit` method, a time series without missing values. The class of object will be preserved.

**See Also**

[diff](#); [na.omit](#), [na.fail](#), [na.contiguous](#).

---

ts.plot

---

*Plot Multiple Time Series*

---

**Description**

Plot several time series on a common plot. Unlike [plot.ts](#) the series can have a different time bases, but they should have the same frequency.

**Usage**

```
ts.plot(..., gpars = list())
```

**Arguments**

|       |                                                                                                                               |
|-------|-------------------------------------------------------------------------------------------------------------------------------|
| ...   | one or more univariate or multivariate time series.                                                                           |
| gpars | list of named graphics parameters to be passed to the plotting functions. Those commonly used can be supplied directly in ... |

**Value**

None.

**Note**

Although this can be used for a single time series, `plot` is easier to use and is preferred.

**See Also**

[plot.ts](#)

**Examples**

```
require(graphics)

ts.plot(ldeaths, mdeaths, fdeaths,
        gpars=list(xlab="year", ylab="deaths", lty=c(1:3)))
```

---

|          |                                     |
|----------|-------------------------------------|
| ts.union | <i>Bind Two or More Time Series</i> |
|----------|-------------------------------------|

---

**Description**

Bind time series which have a common frequency. `ts.union` pads with NAs to the total time coverage, `ts.intersect` restricts to the time covered by all the series.

**Usage**

```
ts.intersect(..., dframe = FALSE)
ts.union(..., dframe = FALSE)
```

**Arguments**

|        |                                                                                                  |
|--------|--------------------------------------------------------------------------------------------------|
| ...    | two or more univariate or multivariate time series, or objects which can coerced to time series. |
| dframe | logical; if TRUE return the result as a data frame.                                              |

**Details**

As a special case, ... can contain vectors or matrices of the same length as the combined time series of the time series present, as well as those of a single row.

**Value**

A time series object if `dframe` is FALSE, otherwise a data frame.

**See Also**

[cbind](#).

**Examples**

```
ts.union(mdeaths, fdeaths)
cbind(mdeaths, fdeaths) # same as the previous line
ts.intersect(window(mdeaths, 1976), window(fdeaths, 1974, 1978))

sales1 <- ts.union(BJsales, lead = BJsales.lead)
ts.intersect(sales1, lead3 = lag(BJsales.lead, -3))
```

---

`tsdiag`*Diagnostic Plots for Time-Series Fits*

---

### Description

A generic function to plot time-series diagnostics.

### Usage

```
tsdiag(object, gof.lag, ...)
```

### Arguments

|                      |                                                                   |
|----------------------|-------------------------------------------------------------------|
| <code>object</code>  | a fitted time-series model                                        |
| <code>gof.lag</code> | the maximum number of lags for a Portmanteau goodness-of-fit test |
| <code>...</code>     | further arguments to be passed to particular methods              |

### Details

This is a generic function. It will generally plot the residuals, often standardized, the autocorrelation function of the residuals, and the p-values of a Portmanteau test for all lags up to `gof.lag`.

The methods for [arima](#) and [StructTS](#) objects plots residuals scaled by the estimate of their (individual) variance, and use the Ljung–Box version of the portmanteau test.

### Value

None. Diagnostics are plotted.

### See Also

[arima](#), [StructTS](#), [Box.test](#)

### Examples

```
require(graphics)

fit <- arima(lh, c(1,0,0))
tsdiag(fit)

## see also examples(arima)

(fit <- StructTS(log10(JohnsonJohnson), type = "BSM"))
tsdiag(fit)
```

tsp

*'Tsp' Attribute of Time-Series-like Objects***Description**

tsp returns the tsp attribute (or NULL). It is included for compatibility with S version 2. `tsp<-` sets the tsp attribute. `hasTsp` ensures x has a tsp attribute, by adding one if needed.

**Usage**

```
tsp(x)
tsp(x) <- value
hasTsp(x)
```

**Arguments**

x                      a vector or matrix or univariate or multivariate time-series.  
 value                  a numeric vector of length 3 or NULL.

**Details**

The tsp attribute gives the start time *in time units*, the end time and the frequency (the number of observations per unit of time, e.g. 12 for a monthly series). The frequency may be fractional, see [ts](#).

Assignments are checked for consistency.

Assigning NULL which removes the tsp attribute *and* any "ts" (or "mts") class of x.

**Value**

An object which differs from x only in the tsp attribute (unless NULL is assigned).

`hasTsp` adds, if needed, an attribute with a start time and frequency of 1 and end time [NROW](#)(x).

**References**

Becker, R. A., Chambers, J. M. and Wilks, A. R. (1988) *The New S Language*. Wadsworth & Brooks/Cole.

**See Also**

[ts](#), [time](#), [start](#).

---

tsSmooth

*Use Fixed-Interval Smoothing on Time Series*

---

**Description**

Performs fixed-interval smoothing on a univariate time series via a state-space model. Fixed-interval smoothing gives the best estimate of the state at each time point based on the whole observed series.

**Usage**

```
tsSmooth(object, ...)
```

**Arguments**

object            a time-series fit. Currently only class "[StructTS](#)" is supported  
 ...               possible arguments for future methods.

**Value**

A time series, with as many dimensions as the state space and results at each time point of the original series. (For seasonal models, only the current seasonal component is returned.)

**Author(s)**

B. D. Ripley

---

Tukey

*The Studentized Range Distribution*

---

**Description**

Functions of the distribution of the studentized range,  $R/s$ , where  $R$  is the range of a standard normal sample and  $df \times s^2$  is independently distributed as chi-squared with  $df$  degrees of freedom, see [pchisq](#).

**Usage**

```
ptukey(q, nmeans, df, nranges = 1, lower.tail = TRUE, log.p = FALSE)
qtukey(p, nmeans, df, nranges = 1, lower.tail = TRUE, log.p = FALSE)
```

## Arguments

|                         |                                                                                       |
|-------------------------|---------------------------------------------------------------------------------------|
| <code>q</code>          | vector of quantiles.                                                                  |
| <code>p</code>          | vector of probabilities.                                                              |
| <code>nmeans</code>     | sample size for range (same for each group).                                          |
| <code>df</code>         | degrees of freedom for $s$ (see below).                                               |
| <code>nranges</code>    | number of <i>groups</i> whose <b>maximum</b> range is considered.                     |
| <code>log.p</code>      | logical; if TRUE, probabilities <code>p</code> are given as $\log(p)$ .               |
| <code>lower.tail</code> | logical; if TRUE (default), probabilities are $P[X \leq x]$ , otherwise, $P[X > x]$ . |

## Details

If  $n_g = \text{nranges}$  is greater than one,  $R$  is the *maximum* of  $n_g$  groups of `nmeans` observations each.

## Value

`ptukey` gives the distribution function and `qtukey` its inverse, the quantile function.

The length of the result is the maximum of the lengths of the numerical arguments. The other numerical arguments are recycled to that length. Only the first elements of the logical arguments are used.

## Note

A Legendre 16-point formula is used for the integral of `ptukey`. The computations are relatively expensive, especially for `qtukey` which uses a simple secant method for finding the inverse of `ptukey`. `qtukey` will be accurate to the 4th decimal place.

## Source

`qtukey` is in part adapted from Odeh and Evans (1974).

## Examples

```
if(interactive())
  curve(ptukey(x, nm = 6, df = 5), from = -1, to = 8, n = 101)
  (ptt <- ptukey(0:10, 2, df = 5))
  (qtt <- qtukey(.95, 2, df = 2:11))
  ## The precision may be not much more than about 8 digits:
  summary(abs(.95 - ptukey(qtt, 2, df = 2:11)))
```

---

TukeyHSD

---

*Compute Tukey Honest Significant Differences*

---

### Description

Create a set of confidence intervals on the differences between the means of the levels of a factor with the specified family-wise probability of coverage. The intervals are based on the Studentized range statistic, Tukey's 'Honest Significant Difference' method.

### Usage

```
TukeyHSD(x, which, ordered = FALSE, conf.level = 0.95, ...)
```

### Arguments

|            |                                                                                                                                                                                                                                                                                                                            |
|------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| x          | A fitted model object, usually an <a href="#">aov</a> fit.                                                                                                                                                                                                                                                                 |
| which      | A character vector listing terms in the fitted model for which the intervals should be calculated. Defaults to all the terms.                                                                                                                                                                                              |
| ordered    | A logical value indicating if the levels of the factor should be ordered according to increasing average in the sample before taking differences. If ordered is true then the calculated differences in the means will all be positive. The significant differences will be those for which the lwr end point is positive. |
| conf.level | A numeric value between zero and one giving the family-wise confidence level to use.                                                                                                                                                                                                                                       |
| ...        | Optional additional arguments. None are used at present.                                                                                                                                                                                                                                                                   |

### Details

This is a generic function: the description here applies to the method for fits of class "aov".

When comparing the means for the levels of a factor in an analysis of variance, a simple comparison using t-tests will inflate the probability of declaring a significant difference when it is not in fact present. This because the intervals are calculated with a given coverage probability for each interval but the interpretation of the coverage is usually with respect to the entire family of intervals.

John Tukey introduced intervals based on the range of the sample means rather than the individual differences. The intervals returned by this function are based on this Studentized range statistics.

The intervals constructed in this way would only apply exactly to balanced designs where there are the same number of observations made at each level of the factor. This function incorporates an adjustment for sample size that produces sensible intervals for mildly unbalanced designs.

If which specifies non-factor terms these will be dropped with a warning: if no terms are left this is an error.

### Value

A list of class `c("multicomp", "TukeyHSD")`, with one component for each term requested in which. Each component is a matrix with columns `diff` giving the difference in the observed means, `lwr` giving the lower end point of the interval, `upr` giving the upper end point and `p adj` giving the p-value after adjustment for the multiple comparisons.

There are print and plot methods for class "TukeyHSD". The plot method does not accept `xlab`, `ylab` or `main` arguments and creates its own values for each plot.

summary(fm1 <- aov(breaks ~ wool + tension, data = warpbreaks))
TukeyHSD(fm1, "tension", ordered = TRUE)
plot(TukeyHSD(fm1, "tension"))
```

Uniform

*The Uniform Distribution***Description**

These functions provide information about the uniform distribution on the interval from min to max. `dunif` gives the density, `punif` gives the distribution function `qunif` gives the quantile function and `runif` generates random deviates.

**Usage**

```
dunif(x, min = 0, max = 1, log = FALSE)
punif(q, min = 0, max = 1, lower.tail = TRUE, log.p = FALSE)
qunif(p, min = 0, max = 1, lower.tail = TRUE, log.p = FALSE)
runif(n, min = 0, max = 1)
```

**Arguments**

|                         |                                                                                                           |
|-------------------------|-----------------------------------------------------------------------------------------------------------|
| <code>x, q</code>       | vector of quantiles.                                                                                      |
| <code>p</code>          | vector of probabilities.                                                                                  |
| <code>n</code>          | number of observations. If <code>length(n) &gt; 1</code> , the length is taken to be the number required. |
| <code>min, max</code>   | lower and upper limits of the distribution. Must be finite.                                               |
| <code>log, log.p</code> | logical; if TRUE, probabilities <code>p</code> are given as $\log(p)$ .                                   |
| <code>lower.tail</code> | logical; if TRUE (default), probabilities are $P[X \leq x]$ , otherwise, $P[X > x]$ .                     |

## Details

If `min` or `max` are not specified they assume the default values of 0 and 1 respectively.

The uniform distribution has density

$$f(x) = \frac{1}{\max - \min}$$

for  $\min \leq x \leq \max$ .

For the case of  $u := \min == \max$ , the limit case of  $X \equiv u$  is assumed, although there is no density in that case and `dunif` will return NaN (the error condition).

`runif` will not generate either of the extreme values unless  $\max = \min$  or  $\max - \min$  is small compared to  $\min$ , and in particular not for the default arguments.

## Value

`dunif` gives the density, `punif` gives the distribution function, `qunif` gives the quantile function, and `runif` generates random deviates.

The length of the result is determined by `n` for `runif`, and is the maximum of the lengths of the numerical arguments for the other functions.

The numerical arguments other than `n` are recycled to the length of the result. Only the first elements of the logical arguments are used.

## Note

The characteristics of output from pseudo-random number generators (such as precision and periodicity) vary widely. See [.Random.seed](#) for more information on R's random number generation algorithms.

## Examples

```
u <- runif(20)

## The following relations always hold :
punif(u) == u
dunif(u) == 1

var(runif(10000)) #- ~ = 1/12 = .08333
```

## Description

The function `uniroot` searches the interval from `lower` to `upper` for a root (i.e., zero) of the function `f` with respect to its first argument.

Setting `extendInt` to a non-"no" string, means searching for the correct interval = `c(lower,upper)` if `sign(f(x))` does not satisfy the requirements at the interval end points; see the 'Details' section.

## Usage

```
uniroot(f, interval, ...,
        lower = min(interval), upper = max(interval),
        f.lower = f(lower, ...), f.upper = f(upper, ...),
        extendInt = c("no", "yes", "downX", "upX"), check.conv = FALSE,
        tol = .Machine$double.eps^0.25, maxiter = 1000, trace = 0)
```

## Arguments

|                               |                                                                                                                                                                                                                                                                                              |
|-------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>f</code>                | the function for which the root is sought.                                                                                                                                                                                                                                                   |
| <code>interval</code>         | a vector containing the end-points of the interval to be searched for the root.                                                                                                                                                                                                              |
| <code>...</code>              | additional named or unnamed arguments to be passed to <code>f</code>                                                                                                                                                                                                                         |
| <code>lower, upper</code>     | the lower and upper end points of the interval to be searched.                                                                                                                                                                                                                               |
| <code>f.lower, f.upper</code> | the same as <code>f(upper)</code> and <code>f(lower)</code> , respectively. Passing these values from the caller where they are often known is more economical as soon as <code>f()</code> contains non-trivial computations.                                                                |
| <code>extendInt</code>        | character string specifying if the interval <code>c(lower,upper)</code> should be extended or directly produce an error when <code>f()</code> does not have differing signs at the end-points. The default, "no", keeps the search interval and hence produces an error. Can be abbreviated. |
| <code>check.conv</code>       | logical indicating whether a convergence warning should be caught as an error and if non-convergence in <code>maxiter</code> iterations should be an error instead of a warning.                                                                                                             |
| <code>tol</code>              | the desired accuracy (convergence tolerance).                                                                                                                                                                                                                                                |
| <code>maxiter</code>          | the maximum number of iterations.                                                                                                                                                                                                                                                            |
| <code>trace</code>            | integer number; if positive, tracing information is produced. Higher values giving more details.                                                                                                                                                                                             |

## Details

Note that arguments after `...` must be matched exactly.

Either `interval` or both `lower` and `upper` must be specified: the upper endpoint must be strictly larger than the lower endpoint. The function values at the endpoints must be of opposite signs (or zero), for `extendInt="no"`, the default. Otherwise, if `extendInt="yes"`, the interval is extended on both sides, in search of a sign change, i.e., until the search interval  $[l, u]$  satisfies  $f(l) \cdot f(u) \leq 0$ .

If it is *known how*  $f$  changes sign at the root  $x_0$ , that is, if the function is increasing or decreasing there, `extendInt` can (and typically should) be specified as "upX" (for "upward crossing") or "downX", respectively. Equivalently, define  $S := \pm 1$ , to require  $S = \text{sign}(f(x_0 + \epsilon))$  at the solution. In that case, the search interval  $[l, u]$  possibly is extended to be such that  $S \cdot f(l) \leq 0$  and  $S \cdot f(u) \geq 0$ .

`uniroot()` uses Fortran subroutine `zeroin` (from Netlib) based on algorithms given in the reference below. They assume a continuous function (which then is known to have at least one root in the interval).

Convergence is declared either if  $f(x) == 0$  or the change in  $x$  for one step of the algorithm is less than `tol` (plus an allowance for representation error in  $x$ ).

If the algorithm does not converge in `maxiter` steps, a warning is printed and the current approximation is returned.

$f$  will be called as  $f(x, \dots)$  for a numeric value of  $x$ .

The argument passed to  $f$  has special semantics and used to be shared between calls. The function should not copy it.

### Value

A list with at least five components: `root` and `f.root` give the location of the root and the value of the function evaluated at that point. `iter` and `estim.prec` give the number of iterations used and an approximate estimated precision for `root`. (If the root occurs at one of the endpoints, the estimated precision is NA.) `init.it` contains the number of *initial* `extendInt` iterations if there were any and is NA otherwise. In the case of such `extendInt` iterations, `iter` contains the sum of these and the `zeroin` iterations.

Further components may be added in the future.

### Examples

```
require(utils) # for str

## some platforms hit zero exactly on the first step:
## if so the estimated precision is 2/3.
f <- function(x, a) x - a
str(xmin <- uniroot(f, c(0, 1), tol = 0.0001, a = 1/3))

## handheld calculator example: fixed point of cos(.):
uniroot(function(x) cos(x) - x, lower = -pi, upper = pi, tol = 1e-9)$root

str(uniroot(function(x) x*(x^2-1) + .5, lower = -2, upper = 2,
  tol = 0.0001))
```

```

str(uniroot(function(x) x*(x^2-1) + .5, lower = -2, upper = 2,
           tol = 1e-10))

## Find the smallest value x for which exp(x) > 0 (numerically):
r <- uniroot(function(x) 1e80*exp(x) - 1e-300, c(-1000, 0), tol = 1e-15)
str(r, digits.d = 15) # around -745, depending on the platform.

exp(r$root)      # = 0, but not for r$root * 0.999...
minexp <- r$root * (1 - 10*.Machine$double.eps)
exp(minexp)      # typically denormalized

##--- uniroot() with new interval extension + checking features: -----

f1 <- function(x) (121 - x^2)/(x^2+1)
f2 <- function(x) exp(-x)*(x - 12)

try(uniroot(f1, c(0,10)))
try(uniroot(f2, c(0, 2)))
##--> error: f() .. end points not of opposite sign

## where as 'extendInt="yes"' simply first enlarges the search interval:
u1 <- uniroot(f1, c(0,10),extendInt="yes", trace=1)
u2 <- uniroot(f2, c(0,2), extendInt="yes", trace=2)
stopifnot(all.equal(u1$root, 11, tolerance = 1e-5),
          all.equal(u2$root, 12, tolerance = 6e-6))

## The *danger* of interval extension:
## No way to find a zero of a positive function, but
## numerically, f(-|M|) becomes zero :
u3 <- uniroot(exp, c(0,2), extendInt="yes", trace=TRUE)

## Nonsense example (must give an error):
tools::assertCondition( uniroot(function(x) 1, 0:1, extendInt="yes"),
                        "error", verbose=TRUE)

## Convergence checking :
sinc <- function(x) ifelse(x == 0, 1, sin(x)/x)
curve(sinc, -6,18); abline(h=0,v=0, lty=3, col=adjustcolor("gray", 0.8))

uniroot(sinc, c(0,5), extendInt="yes", maxiter=4) #-> "just" a warning

## now with check.conv=TRUE, must signal a convergence error :

uniroot(sinc, c(0,5), extendInt="yes", maxiter=4, check.conv=TRUE)

### Weibull cumulative hazard (example origin, Ravi Varadhan):
cumhaz <- function(t, a, b) b * (t/b)^a
froot <- function(x, u, a, b) cumhaz(x, a, b) - u

n <- 1000
u <- -log(runif(n))
a <- 1/2
b <- 1
## Find failure times

```

```

ru <- sapply(u, function(x)
  uniroot(froot, u=x, a=a, b=b, interval= c(1.e-14, 1e04),
    extendInt="yes")$root)
ru2 <- sapply(u, function(x)
  uniroot(froot, u=x, a=a, b=b, interval= c(0.01, 10),
    extendInt="yes")$root)
stopifnot(all.equal(ru, ru2, tolerance = 6e-6))

r1 <- uniroot(froot, u= 0.99, a=a, b=b, interval= c(0.01, 10),
  extendInt="up")
stopifnot(all.equal(0.99, cumhaz(r1$root, a=a, b=b)))

## An error if 'extendInt' assumes "wrong zero-crossing direction":

uniroot(froot, u= 0.99, a=a, b=b, interval= c(0.1, 10), extendInt="down")

```

update

*Update and Re-fit a Model Call***Description**

update will update and (by default) re-fit a model. It does this by extracting the call stored in the object, updating the call and (by default) evaluating that call. Sometimes it is useful to call update with only one argument, for example if the data frame has been corrected.

“Extracting the call” in update() and similar functions uses getCall() which itself is a (S3) generic function with a default method that simply gets x\$call.

Because of this, update() will often work (via its default method) on new model classes, either automatically, or by providing a simple getCall() method for that class.

**Usage**

```

update(object, ...)
## Default S3 method:
update(object, formula., ..., evaluate = TRUE)

getCall(x, ...)

```

**Arguments**

|           |                                                                                                                  |
|-----------|------------------------------------------------------------------------------------------------------------------|
| object, x | An existing fit from a model function such as lm, glm and many others.                                           |
| formula.  | Changes to the formula – see update.formula for details.                                                         |
| ...       | Additional arguments to the call, or arguments with changed values. Use name = NULL to remove the argument name. |
| evaluate  | If true evaluate the new call else return the call.                                                              |

**Value**

If evaluate = TRUE the fitted object, otherwise the updated call.

|----------------|-----------------------|
| update.formula | <i>Model Updating</i> |
|----------------|-----------------------|

---

## Description

`update.formula` is used to update model formulae. This typically involves adding or dropping terms, but updates can be more general.

## Usage

```
## S3 method for class 'formula'
update(old, new, ...)
```

## Arguments

|                  |                                                            |
|------------------|------------------------------------------------------------|
| <code>old</code> | a model formula to be updated.                             |
| <code>new</code> | a formula giving a template which specifies how to update. |
| <code>...</code> | further arguments passed to or from other methods.         |

## Details

Either or both of `old` and `new` can be objects such as length-one character vectors which can be coerced to a formula via [as.formula](#).

The function works by first identifying the *left-hand side* and *right-hand side* of the old formula. It then examines the new formula and substitutes the *lhs* of the old formula for any occurrence of ‘.’ on the left of new, and substitutes the *rhs* of the old formula for any occurrence of ‘.’ on the right of new. The result is then simplified via [terms.formula](#)(simplify = TRUE).

Value

The updated formula is returned. The environment of the result is that of old.

See Also

[terms](#), [model.matrix](#).

Examples

```
update(y ~ x,      ~ . + x2) #> y ~ x + x2
update(y ~ x, log(.) ~ . ) #> log(y) ~ x
update(. ~ u+v, res ~ . ) #> res ~ u + v
```

---

|          |                                        |
|----------|----------------------------------------|
| var.test | <i>F Test to Compare Two Variances</i> |
|----------|----------------------------------------|

---

Description

Performs an F test to compare the variances of two samples from normal populations.

Usage

```
var.test(x, ...)
```

```
## Default S3 method:
var.test(x, y, ratio = 1,
         alternative = c("two.sided", "less", "greater"),
         conf.level = 0.95, ...)
```

```
## S3 method for class 'formula'
var.test(formula, data, subset, na.action, ...)
```

Arguments

|             |                                                                                                                                                                                                |
|-------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| x, y        | numeric vectors of data values, or fitted linear model objects (inheriting from class "lm").                                                                                                   |
| ratio       | the hypothesized ratio of the population variances of x and y.                                                                                                                                 |
| alternative | a character string specifying the alternative hypothesis, must be one of "two.sided" (default), "greater" or "less". You can specify just the initial letter.                                  |
| conf.level  | confidence level for the returned confidence interval.                                                                                                                                         |
| formula     | a formula of the form lhs ~ rhs where lhs is a numeric variable giving the data values and rhs a factor with two levels giving the corresponding groups.                                       |
| data        | an optional matrix or data frame (or similar: see <a href="#">model.frame</a> ) containing the variables in the formula formula. By default the variables are taken from environment(formula). |
| subset      | an optional vector specifying a subset of observations to be used.                                                                                                                             |
| na.action   | a function which indicates what should happen when the data contain NAs. Defaults to getOption("na.action").                                                                                   |
| ...         | further arguments to be passed to or from methods.                                                                                                                                             |

## Details

The null hypothesis is that the ratio of the variances of the populations from which  $x$  and  $y$  were drawn, or in the data to which the linear models  $x$  and  $y$  were fitted, is equal to `ratio`.

## Value

A list with class "htest" containing the following components:

|                          |                                                                         |
|--------------------------|-------------------------------------------------------------------------|
| <code>statistic</code>   | the value of the F test statistic.                                      |
| <code>parameter</code>   | the degrees of the freedom of the F distribution of the test statistic. |
| <code>p.value</code>     | the p-value of the test.                                                |
| <code>conf.int</code>    | a confidence interval for the ratio of the population variances.        |
| <code>estimate</code>    | the ratio of the sample variances of $x$ and $y$ .                      |
| <code>null.value</code>  | the ratio of population variances under the null.                       |
| <code>alternative</code> | a character string describing the alternative hypothesis.               |
| <code>method</code>      | the character string "F test to compare two variances".                 |
| <code>data.name</code>   | a character string giving the names of the data.                        |

## See Also

[bartlett.test](#) for testing homogeneity of variances in more than two samples from normal distributions; [ansari.test](#) and [mood.test](#) for two rank based (nonparametric) two-sample tests for difference in scale.

## Examples

```
x <- rnorm(50, mean = 0, sd = 2)
y <- rnorm(30, mean = 1, sd = 1)
var.test(x, y) # Do x and y have the same variance?
var.test(lm(x ~ 1), lm(y ~ 1)) # The same.
```

---

varimax

*Rotation Methods for Factor Analysis*

---

## Description

These functions ‘rotate’ loading matrices in factor analysis.

## Usage

```
varimax(x, normalize = TRUE, eps = 1e-5)
promax(x, m = 4)
```

## Arguments

|                        |                                                                                                                                                    |
|------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>         | A loadings matrix, with $p$ rows and $k < p$ columns                                                                                               |
| <code>m</code>         | The power used the target for promax. Values of 2 to 4 are recommended.                                                                            |
| <code>normalize</code> | logical. Should Kaiser normalization be performed? If so the rows of $x$ are re-scaled to unit length before rotation, and scaled back afterwards. |
| <code>eps</code>       | The tolerance for stopping: the relative change in the sum of singular values.                                                                     |

## Details

These seek a ‘rotation’ of the factors  $x \times x^T$  that aims to clarify the structure of the loadings matrix. The matrix  $T$  is a rotation (possibly with reflection) for `varimax`, but a general linear transformation for `promax`, with the variance of the factors being preserved.

## Value

A list with components

|                       |                                                                                          |
|-----------------------|------------------------------------------------------------------------------------------|
| <code>loadings</code> | The ‘rotated’ loadings matrix, $x \times x^T$ <code>rotmat</code> , of class “loadings”. |
| <code>rotmat</code>   | The ‘rotation’ matrix.                                                                   |

varimax(loadings(fa), normalize = FALSE)
promax(loadings(fa))
```

---

vcov

*Calculate Variance-Covariance Matrix for a Fitted Model Object*

---

## Description

Returns the variance-covariance matrix of the main parameters of a fitted model object. The “main” parameters of model correspond to those returned by `coef`, and typically do not contain a nuisance scale parameter (`sigma`).

## Usage

```
vcov(object, ...)
## S3 method for class 'lm'
vcov(object, complete = TRUE, ...)
## and also for '[summary.]glm' and 'mlm'
## S3 method for class 'aov'
vcov(object, complete = FALSE, ...)

.vcov.aliased.aliased, vc, complete = TRUE)
```

**Arguments**

|          |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| object   | a fitted model object, typically. Sometimes also a <code>summary()</code> object of such a fitted model.                                                                                                                                                                                                                                                                                                                                                                                    |
| complete | for the <code>aov</code> , <code>lm</code> , <code>glm</code> , <code>mlm</code> , and where applicable <code>summary.lm</code> etc methods: logical indicating if the full variance-covariance matrix should be returned also in case of an over-determined system where some coefficients are undefined and <code>coef(.)</code> contains NAs correspondingly. When <code>complete = TRUE</code> , <code>vcov()</code> is compatible with <code>coef()</code> also in this singular case. |
| ...      | additional arguments for method functions. For the <code>glm</code> method this can be used to pass a dispersion parameter.                                                                                                                                                                                                                                                                                                                                                                 |
| aliased  | a <b>logical</b> vector typically identical to <code>is.na(coef(.))</code> indicating which coefficients are ‘aliased’.                                                                                                                                                                                                                                                                                                                                                                     |
| vc       | a variance-covariance matrix, typically “incomplete”, i.e., with no rows and columns for aliased coefficients.                                                                                                                                                                                                                                                                                                                                                                              |

**Details**

`vcov()` is a generic function and functions with names beginning in `vcov.` will be methods for this function. Classes with methods for this function include: `lm`, `mlm`, `glm`, `nls`, `summary.lm`, `summary.glm`, `negbin`, `polr`, `rlm` (in package **MASS**), `multinom` (in package **nnet**) `gls`, `lme` (in package **nlme**), `coxph` and `survreg` (in package **survival**).

(`vcov()` methods for summary objects allow more efficient and still encapsulated access when both `summary(mod)` and `vcov(mod)` are needed.)

`.vcov.aliased()` is an auxiliary function useful for `vcov` method implementations which have to deal with singular model fits encoded via NA coefficients: It augments a `vcov`-matrix `vc` by NA rows and columns where needed, i.e., when some entries of `aliased` are true and `vc` is of smaller dimension than `length(aliased)`.

**Value**

A matrix of the estimated covariances between the parameter estimates in the linear or non-linear predictor of the model. This should have row and column names corresponding to the parameter names given by the `coef` method.

When some coefficients of the (linear) model are undetermined and hence NA because of linearly dependent terms (or an “over specified” model), also called “aliased”, see [alias](#), then since R version 3.5.0, `vcov()` (iff `complete = TRUE`, i.e., by default for `lm` etc, but not for `aov`) contains corresponding rows and columns of NAs, wherever `coef()` has always contained such NAs.

**Description**

Density, distribution function, quantile function and random generation for the Weibull distribution with parameters shape and scale.

**Usage**

```
dweibull(x, shape, scale = 1, log = FALSE)
pweibull(q, shape, scale = 1, lower.tail = TRUE, log.p = FALSE)
qweibull(p, shape, scale = 1, lower.tail = TRUE, log.p = FALSE)
rweibull(n, shape, scale = 1)
```

**Arguments**

|                           |                                                                                                           |
|---------------------------|-----------------------------------------------------------------------------------------------------------|
| <code>x, q</code>         | vector of quantiles.                                                                                      |
| <code>p</code>            | vector of probabilities.                                                                                  |
| <code>n</code>            | number of observations. If <code>length(n) &gt; 1</code> , the length is taken to be the number required. |
| <code>shape, scale</code> | shape and scale parameters, the latter defaulting to 1.                                                   |
| <code>log, log.p</code>   | logical; if TRUE, probabilities <code>p</code> are given as <code>log(p)</code> .                         |
| <code>lower.tail</code>   | logical; if TRUE (default), probabilities are $P[X \leq x]$ , otherwise, $P[X > x]$ .                     |

**Details**

The Weibull distribution with shape parameter  $a$  and scale parameter  $\sigma$  has density given by

$$f(x) = (a/\sigma)(x/\sigma)^{a-1} \exp(-(x/\sigma)^a)$$

for  $x > 0$ . The cumulative distribution function is  $F(x) = 1 - \exp(-(x/\sigma)^a)$  on  $x > 0$ , the mean is  $E(X) = \sigma\Gamma(1 + 1/a)$ , and the  $Var(X) = \sigma^2(\Gamma(1 + 2/a) - (\Gamma(1 + 1/a))^2)$ .

**Value**

`dweibull` gives the density, `pweibull` gives the distribution function, `qweibull` gives the quantile function, and `rweibull` generates random deviates.

Invalid arguments will result in return value NaN, with a warning.

The length of the result is determined by `n` for `rweibull`, and is the maximum of the lengths of the numerical arguments for the other functions.

The numerical arguments other than `n` are recycled to the length of the result. Only the first elements of the logical arguments are used.

**Note**

The cumulative hazard  $H(t) = -\log(1 - F(t))$  is

```
-pweibull(t, a, b, lower = FALSE, log = TRUE)
```

which is just  $H(t) = (t/b)^a$ .

**Source**

`[dpq]weibull` are calculated directly from the definitions. `rweibull` uses inversion.

**See Also**

[Distributions](#) for other standard distributions, including the [Exponential](#) which is a special case of the Weibull distribution.

**Examples**

```
x <- c(0, rlnorm(50))
all.equal(dweibull(x, shape = 1), dexp(x))
all.equal(pweibull(x, shape = 1, scale = pi), pexp(x, rate = 1/pi))
## Cumulative hazard H():
all.equal(pweibull(x, 2.5, pi, lower.tail = FALSE, log.p = TRUE),
          -(x/pi)^2.5, tolerance = 1e-15)
all.equal(qweibull(x/11, shape = 1, scale = pi), qexp(x/11, rate = 1/pi))
```

weighted.mean

*Weighted Arithmetic Mean***Description**

Compute a weighted mean.

**Usage**

```
weighted.mean(x, w, ...)

## Default S3 method:
weighted.mean(x, w, ..., na.rm = FALSE)
```

**Arguments**

|                    |                                                                                                                            |
|--------------------|----------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>     | an object containing the values whose weighted mean is to be computed.                                                     |
| <code>w</code>     | a numerical vector of weights the same length as <code>x</code> giving the weights to use for elements of <code>x</code> . |
| <code>...</code>   | arguments to be passed to or from methods.                                                                                 |
| <code>na.rm</code> | a logical value indicating whether NA values in <code>x</code> should be stripped before the computation proceeds.         |

**Details**

This is a generic function and methods can be defined for the first argument `x`: apart from the default methods there are methods for the date-time classes "POSIXct", "POSIXlt", "difftime" and "Date". The default method will work for any numeric-like object for which `[]`, multiplication, division and [sum](#) have suitable methods, including complex vectors.

If `w` is missing then all elements of `x` are given the same weight, otherwise the weights are normalized to sum to one (if possible: if their sum is zero or infinite the value is likely to be NaN).

Missing values in `w` are not handled specially and so give a missing value as the result. However, zero weights *are* handled specially and the corresponding `x` values are omitted from the sum.

**Value**

For the default method, a length-one numeric vector.

**See Also**[mean](#)**Examples**

```
## GPA from Siegel 1994
wt <- c(5, 5, 4, 1)/15
x <- c(3.7, 3.3, 3.5, 2.8)
xm <- weighted.mean(x, wt)
```

---

|                    |                                   |
|--------------------|-----------------------------------|
| weighted.residuals | <i>Compute Weighted Residuals</i> |
|--------------------|-----------------------------------|

---

**Description**

Computed weighted residuals from a linear model fit.

**Usage**

```
weighted.residuals(obj, drop0 = TRUE)
```

**Arguments**

|       |                                                                          |
|-------|--------------------------------------------------------------------------|
| obj   | R object, typically of class <a href="#">lm</a> or <a href="#">glm</a> . |
| drop0 | logical. If TRUE, drop all cases with <a href="#">weights</a> == 0.      |

**Details**

Weighted residuals are based on the deviance residuals, which for a [lm](#) fit are the raw residuals  $R_i$  multiplied by  $\sqrt{w_i}$ , where  $w_i$  are the weights as specified in [lm](#)'s call.

Dropping cases with weights zero is compatible with [influence](#) and related functions.

**Value**

Numeric vector of length  $n'$ , where  $n'$  is the number of non-0 weights (drop0 = TRUE) or the number of observations, otherwise.

**See Also**

[residuals](#), [lm.influence](#), etc.

**Examples**

```
## following on from example(lm)

all.equal(weighted.residuals(lm.D9),
          residuals(lm.D9))

x <- 1:10
w <- 0:9
y <- rnorm(x)
weighted.residuals(lmxy <- lm(y ~ x, weights = w))
weighted.residuals(lmxy, drop0 = FALSE)
```

---

|         |                              |
|---------|------------------------------|
| weights | <i>Extract Model Weights</i> |
|---------|------------------------------|

---

**Description**

weights is a generic function which extracts fitting weights from objects returned by modeling functions.

Methods can make use of [napredict](#) methods to compensate for the omission of missing values. The default methods does so.

**Usage**

```
weights(object, ...)
```

**Arguments**

|        |                                                                    |
|--------|--------------------------------------------------------------------|
| object | an object for which the extraction of model weights is meaningful. |
| ...    | other arguments passed to methods.                                 |

**Value**

Weights extracted from the object object: the default method looks for component "weights" and if not NULL calls [napredict](#) on it.

**References**

Chambers, J. M. and Hastie, T. J. (1992) *Statistical Models in S*. Wadsworth & Brooks/Cole.

---

|             |                                                |
|-------------|------------------------------------------------|
| wilcox.test | <i>Wilcoxon Rank Sum and Signed Rank Tests</i> |
|-------------|------------------------------------------------|

---

**Description**

Performs one- and two-sample Wilcoxon tests on vectors of data; the latter is also known as ‘Mann-Whitney’ test.

**Usage**

```
wilcox.test(x, ...)
```

```
## Default S3 method:
```

```
wilcox.test(x, y = NULL,  
            alternative = c("two.sided", "less", "greater"),  
            mu = 0, paired = FALSE, exact = NULL, correct = TRUE,  
            conf.int = FALSE, conf.level = 0.95,
```

```

        tol.root = 1e-4, digits.rank = Inf, ...)

## S3 method for class 'formula'
wilcox.test(formula, data, subset, na.action = na.pass, ...)

```

### Arguments

|             |                                                                                                                                                                                                                                                                                   |
|-------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| x           | numeric vector of data values. Non-finite (e.g., infinite or missing) values will be omitted.                                                                                                                                                                                     |
| y           | an optional numeric vector of data values: as with x non-finite values will be omitted.                                                                                                                                                                                           |
| alternative | a character string specifying the alternative hypothesis, must be one of "two.sided" (default), "greater" or "less". You can specify just the initial letter.                                                                                                                     |
| mu          | a number specifying an optional parameter used to form the null hypothesis. See 'Details'.                                                                                                                                                                                        |
| paired      | a logical indicating whether you want a paired test.                                                                                                                                                                                                                              |
| exact       | a logical indicating whether an exact p-value should be computed.                                                                                                                                                                                                                 |
| correct     | a logical indicating whether to apply continuity correction in the normal approximation for the p-value.                                                                                                                                                                          |
| conf.int    | a logical indicating whether a confidence interval should be computed.                                                                                                                                                                                                            |
| conf.level  | confidence level of the interval.                                                                                                                                                                                                                                                 |
| tol.root    | (when conf.int is true:) a positive numeric tolerance, used in <a href="#">uniroot</a> (*, tol=tol.root) calls.                                                                                                                                                                   |
| digits.rank | a number; if finite, <a href="#">rank(signif(r, digits.rank))</a> will be used to compute ranks for the test statistic instead of (the default) <a href="#">rank(r)</a> .                                                                                                         |
| formula     | a formula of the form lhs ~ rhs where lhs is a numeric variable giving the data values and rhs either 1 for a one-sample or paired test or a factor with two levels giving the corresponding groups. If lhs is of class "Pair" and rhs is 1, a paired test is done, see Examples. |
| data        | an optional matrix or data frame (or similar: see <a href="#">model.frame</a> ) containing the variables in the formula formula. By default the variables are taken from <a href="#">environment(formula)</a> .                                                                   |
| subset      | an optional vector specifying a subset of observations to be used.                                                                                                                                                                                                                |
| na.action   | a function which indicates what should happen when the data contain <a href="#">NAs</a> .                                                                                                                                                                                         |
| ...         | further arguments to be passed to or from methods. For the formula method, this includes arguments of the default method, but not paired.                                                                                                                                         |

### Details

The formula interface is only applicable for the 2-sample tests.

If only x is given, or if both x and y are given and paired is TRUE, a Wilcoxon signed rank test of the null that the distribution of x (in the one sample case) or of  $x - y$  (in the paired two sample case) is symmetric about  $\mu$  is performed.

Otherwise, if both x and y are given and paired is FALSE, a Wilcoxon rank sum test (equivalent to the Mann-Whitney test: see the Note) is carried out. In this case, the null hypothesis is that the distributions of x and y differ by a location shift of  $\mu$  and the alternative is that they differ by some other location shift (and the one-sided alternative "greater" is that x is shifted to the right of y).

By default (if `exact` is not specified), an exact p-value is computed if the samples contain less than 50 finite values and there are no ties. Otherwise, a normal approximation is used.

For stability reasons, it may be advisable to use rounded data or to set `digits.rank = 7`, say, such that determination of ties does not depend on very small numeric differences (see the example).

Optionally (if argument `conf.int` is true), a nonparametric confidence interval and an estimator for the pseudomedian (one-sample case) or for the difference of the location parameters  $x-y$  is computed. (The pseudomedian of a distribution  $F$  is the median of the distribution of  $(u + v)/2$ , where  $u$  and  $v$  are independent, each with distribution  $F$ . If  $F$  is symmetric, then the pseudomedian and median coincide. See Hollander & Wolfe (1973), page 34.) Note that in the two-sample case the estimator for the difference in location parameters does **not** estimate the difference in medians (a common misconception) but rather the median of the difference between a sample from  $x$  and a sample from  $y$ .

If exact p-values are available, an exact confidence interval is obtained by the algorithm described in Bauer (1972), and the Hodges-Lehmann estimator is employed. Otherwise, the returned confidence interval and point estimate are based on normal approximations. These are continuity-corrected for the interval but *not* the estimate (as the correction depends on the alternative).

With small samples it may not be possible to achieve very high confidence interval coverages. If this happens a warning will be given and an interval with lower coverage will be substituted.

When  $x$  (and  $y$  if applicable) are valid, the function now always returns, also in the `conf.int = TRUE` case when a confidence interval cannot be computed, in which case the interval boundaries and sometimes the estimate now contain `NaN`.

## Value

A list with class "htest" containing the following components:

|                          |                                                                                                             |
|--------------------------|-------------------------------------------------------------------------------------------------------------|
| <code>statistic</code>   | the value of the test statistic with a name describing it.                                                  |
| <code>parameter</code>   | the parameter(s) for the exact distribution of the test statistic.                                          |
| <code>p.value</code>     | the p-value for the test.                                                                                   |
| <code>null.value</code>  | the location parameter $\mu$ .                                                                              |
| <code>alternative</code> | a character string describing the alternative hypothesis.                                                   |
| <code>method</code>      | the type of test applied.                                                                                   |
| <code>data.name</code>   | a character string giving the names of the data.                                                            |
| <code>conf.int</code>    | a confidence interval for the location parameter. (Only present if argument <code>conf.int = TRUE</code> .) |
| <code>estimate</code>    | an estimate of the location parameter. (Only present if argument <code>conf.int = TRUE</code> .)            |

## Warning

This function can use large amounts of memory and stack (and even crash **R** if the stack limit is exceeded) if `exact = TRUE` and one sample is large (several thousands or more).

## Note

The literature is not unanimous about the definitions of the Wilcoxon rank sum and Mann-Whitney tests. The two most common definitions correspond to the sum of the ranks of the first sample with the minimum value  $(m(m + 1)/2$  for a first sample of size  $m$ ) subtracted or not: **R** subtracts. It seems Wilcoxon's original paper used the unadjusted sum of the ranks but subsequent tables subtracted the minimum.

```
wilcox.test(rnorm(10), rnorm(10, 2), conf.int = TRUE)

## Formula interface.
boxplot(Ozone ~ Month, data = airquality)
wilcox.test(Ozone ~ Month, data = airquality,
            subset = Month %in% c(5, 8))

## accuracy in ties determination via 'digits.rank':
wilcox.test(4:2, 3:1, paired=TRUE) # Warning: cannot compute exact p-value with ties
wilcox.test((4:2)/10, (3:1)/10, paired=TRUE) # no ties => *no* warning
wilcox.test((4:2)/10, (3:1)/10, paired=TRUE, digits.rank = 9) # same ties as (4:2, 3:1)
```

---

Wilcoxon

---

*Distribution of the Wilcoxon Rank Sum Statistic*

---

## Description

Density, distribution function, quantile function and random generation for the distribution of the Wilcoxon rank sum statistic obtained from samples with size  $m$  and  $n$ , respectively.

## Usage

```
dwilcox(x, m, n, log = FALSE)
pwilcox(q, m, n, lower.tail = TRUE, log.p = FALSE)
qwilcox(p, m, n, lower.tail = TRUE, log.p = FALSE)
rwilcox(nn, m, n)
```

## Arguments

|                         |                                                                                                            |
|-------------------------|------------------------------------------------------------------------------------------------------------|
| <code>x, q</code>       | vector of quantiles.                                                                                       |
| <code>p</code>          | vector of probabilities.                                                                                   |
| <code>nn</code>         | number of observations. If <code>length(nn) &gt; 1</code> , the length is taken to be the number required. |
| <code>m, n</code>       | numbers of observations in the first and second sample, respectively. Can be vectors of positive integers. |
| <code>log, log.p</code> | logical; if TRUE, probabilities <code>p</code> are given as $\log(p)$ .                                    |
| <code>lower.tail</code> | logical; if TRUE (default), probabilities are $P[X \leq x]$ , otherwise, $P[X > x]$ .                      |

## Details

This distribution is obtained as follows. Let  $x$  and  $y$  be two random, independent samples of size  $m$  and  $n$ . Then the Wilcoxon rank sum statistic is the number of all pairs  $(x[i], y[j])$  for which  $y[j]$  is not greater than  $x[i]$ . This statistic takes values between  $0$  and  $m * n$ , and its mean and variance are  $m * n / 2$  and  $m * n * (m + n + 1) / 12$ , respectively.

If any of the first three arguments are vectors, the recycling rule is used to do the calculations for all combinations of the three up to the length of the longest vector.

**Value**

`dwilcox` gives the density, `pwilcox` gives the distribution function, `qwilcox` gives the quantile function, and `rwilcox` generates random deviates.

The length of the result is determined by `nn` for `rwilcox`, and is the maximum of the lengths of the numerical arguments for the other functions.

The numerical arguments other than `nn` are recycled to the length of the result. Only the first elements of the logical arguments are used.

**Warning**

These functions can use large amounts of memory and stack (and even crash R if the stack limit is exceeded and stack-checking is not in place) if one sample is large (several thousands or more).

**Note**

S-PLUS used a different (but equivalent) definition of the Wilcoxon statistic: see [wilcox.test](#) for details.

**Author(s)**

Kurt Hornik

**Source**

These ("d","p","q") are calculated via recursion, based on `cwilcox(k, m, n)`, the number of choices with statistic `k` from samples of size `m` and `n`, which is itself calculated recursively and the results cached. Then `dwilcox` and `pwilcox` sum appropriate values of `cwilcox`, and `qwilcox` is based on inversion.

`rwilcox` generates a random permutation of ranks and evaluates the statistic. Note that it is based on the same C code as `sample()`, and hence is determined by `.Random.seed`, notably from `RNGkind(sample.kind = .)` which changed with R version 3.6.0.

**See Also**

[wilcox.test](#) to calculate the statistic from data, find p values and so on.

**Examples**

```
require(graphics)

x <- -1:(4*6 + 1)
fx <- dwilcox(x, 4, 6)
Fx <- pwilcox(x, 4, 6)

layout(rbind(1,2), widths = 1, heights = c(3,2))
plot(x, fx, type = "h", col = "violet",
     main = "Probabilities (density) of Wilcoxon-Statist.(n=6, m=4)")
plot(x, Fx, type = "s", col = "blue",
     main = "Distribution of Wilcoxon-Statist.(n=6, m=4)")
abline(h = 0:1, col = "gray20", lty = 2)
layout(1) # set back
```

```

N <- 200
hist(U <- rwilcox(N, m = 4, n = 6), breaks = 0:25 - 1/2,
     border = "red", col = "pink", sub = paste("N =", N))
mtext("N * f(x), f() = true \"density\"", side = 3, col = "blue")
lines(x, N*f(x), type = "h", col = "blue", lwd = 2)
points(x, N*f(x), cex = 2)

## Better is a Quantile-Quantile Plot
qqplot(U, qw <- qwilcox((1:N - 1/2)/N, m = 4, n = 6),
       main = paste("Q-Q-Plot of empirical and theoretical quantiles",
                    "Wilcoxon Statistic, (m=4, n=6)", sep = "\n"))
n <- as.numeric(names(print(tU <- table(U))))
text(n+.2, n+.5, labels = tU, col = "red")

```

window

*Time (Series) Windows***Description**

window is a generic function which extracts the subset of the object *x* observed between the times start and end. If a frequency is specified, the series is then re-sampled at the new frequency.

**Usage**

```

window(x, ...)
## S3 method for class 'ts'
window(x, ...)
## Default S3 method:
window(x, start = NULL, end = NULL,
       frequency = NULL, deltat = NULL, extend = FALSE, ts.eps = getOption("ts.eps"), ...)

window(x, ...) <- value
## S3 replacement method for class 'ts'
window(x, start, end, frequency, deltat, ...) <- value

```

**Arguments**

|                          |                                                                                                                                                                                                                                   |
|--------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>x</i>                 | a time-series (or other object if not replacing values).                                                                                                                                                                          |
| <i>start</i>             | the start time of the period of interest.                                                                                                                                                                                         |
| <i>end</i>               | the end time of the period of interest.                                                                                                                                                                                           |
| <i>frequency, deltat</i> | the new frequency can be specified by either (or both if they are consistent).                                                                                                                                                    |
| <i>extend</i>            | logical. If true, the start and end values are allowed to extend the series. If false, attempts to extend the series give a warning and are ignored.                                                                              |
| <i>ts.eps</i>            | time series comparison tolerance. Frequencies are considered equal if their absolute difference is less than <i>ts.eps</i> and boundaries (length-1 versions of start and end) are checked with fuzz <i>ts.eps/frequency(x)</i> . |
| <i>...</i>               | further arguments passed to or from other methods.                                                                                                                                                                                |
| <i>value</i>             | replacement values.                                                                                                                                                                                                               |

Details

The start and end times can be specified as for [ts](#). If there is no observation at the new `start` or end, the immediately following (`start`) or preceding (`end`) observation time is used.

The replacement function has a method for `ts` objects, and is allowed to extend the series (with a warning). There is no default method.

Value

The value depends on the method. `window.default` will return a vector or matrix with an appropriate [tsp](#) attribute.

`window.ts` differs from `window.default` only in ensuring the result is a `ts` object.

If `extend = TRUE` the series will be padded with NAs if needed.

|-------|-------------------------|
| xtabs | <i>Cross Tabulation</i> |
|-------|-------------------------|

---

Description

Create a contingency table (optionally a sparse matrix) from cross-classifying factors, usually contained in a data frame, using a formula interface.

Usage

```
xtabs(formula = ~., data = parent.frame(), subset, sparse = FALSE,
      na.action, na.rm = FALSE, addNA = FALSE,
      exclude = if(!addNA) c(NA, NaN), drop.unused.levels = FALSE)

## S3 method for class 'xtabs'
print(x, na.print = "", ...)
```

## Arguments

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| formula            | a <a href="#">formula</a> object with the cross-classifying variables (separated by +) on the right-hand side (or an object which can be coerced to a formula). Interactions are not allowed. On the left-hand side, one may optionally give a vector or a matrix of counts; in the latter case, the columns are interpreted as corresponding to the levels of a variable. This is useful if the data have already been tabulated, see the examples below. |
| data               | an optional matrix or data frame (or similar: see <a href="#">model.frame</a> ) containing the variables in the formula formula. By default the variables are taken from <code>environment(formula)</code> .                                                                                                                                                                                                                                               |
| subset             | an optional vector specifying a subset of observations to be used.                                                                                                                                                                                                                                                                                                                                                                                         |
| sparse             | logical specifying if the result should be a <i>sparse</i> matrix, i.e., inheriting from <a href="#">sparseMatrix</a> . Only works for two factors (since there are no higher-order sparse array classes yet).                                                                                                                                                                                                                                             |
| na.action          | a <a href="#">function</a> which indicates what should happen when the variables in formula (or subset) contain NAs. Defaults to <a href="#">na.pass</a> , so <code>na.rm</code> and <code>addNA</code> , respectively, control the handling of missing values for the two sides of the formula. Using <a href="#">na.omit</a> removes any incomplete cases.                                                                                               |
| na.rm              | logical: should missing values on the left-hand side of the formula be treated as zero when computing the <a href="#">sum</a> ?                                                                                                                                                                                                                                                                                                                            |
| addNA              | logical indicating if NAs in the factors should get a separate level and be counted, using <a href="#">addNA</a> (*, ifany=TRUE). This has no effect if <code>na.action = na.omit</code> .                                                                                                                                                                                                                                                                 |
| exclude            | a vector of values to be excluded when forming the set of levels of the classifying factors.                                                                                                                                                                                                                                                                                                                                                               |
| drop.unused.levels | a logical indicating whether to drop unused levels in the classifying factors. If this is FALSE and there are unused levels, the table will contain zero marginals, and a subsequent chi-squared test for independence of the factors will not work.                                                                                                                                                                                                       |
| x                  | an object of class "xtabs".                                                                                                                                                                                                                                                                                                                                                                                                                                |
| na.print           | character string (or NULL) indicating how NA are printed. The default ("") does not show NAs clearly, and <code>na.print = "NA"</code> maybe advisable instead.                                                                                                                                                                                                                                                                                            |
| ...                | further arguments passed to or from other methods.                                                                                                                                                                                                                                                                                                                                                                                                         |

## Details

There is a summary method for contingency table objects created by `table` or `xtabs`(\*, sparse = FALSE), which gives basic information and performs a chi-squared test for independence of factors (note that the function [chisq.test](#) currently only handles 2-d tables).

If a left-hand side is given in formula, its entries are simply summed over the cells corresponding to the right-hand side; this also works if the LHS does not give counts.

For variables in formula which are factors, `exclude` must be specified explicitly; the default exclusions will not be used.

In R versions before 3.4.0, e.g., when `na.action = na.pass`, sometimes zeroes (0) were returned instead of NAs.

In R versions before 4.4.0, when `!addNA` as by default, the default `na.action` was [na.omit](#), effectively treating missing counts as zero.

**Value**

By default, when `sparse = FALSE`, a contingency table in array representation of S3 class `c("xtabs", "table")`, with a `"call"` attribute storing the matched call.

When `sparse = TRUE`, a sparse numeric matrix, specifically an object of S4 class `dgTMatrix` from package **Matrix**.

**See Also**

`table` for traditional cross-tabulation, and `as.data.frame.table` which is the inverse operation of `xtabs` (see the DF example below).

`sparseMatrix` on sparse matrices in package **Matrix**.

**Examples**

```
## 'esoph' has the frequencies of cases and controls for all levels of
## the variables 'agegp', 'alcgp', and 'tobgp'.
xtabs(cbind(ncases, ncontrols) ~ ., data = esoph)
## Output is not really helpful ... flat tables are better:
ftable(xtabs(cbind(ncases, ncontrols) ~ ., data = esoph))
## In particular if we have fewer factors ...
ftable(xtabs(cbind(ncases, ncontrols) ~ agegp, data = esoph))

## This is already a contingency table in array form.
DF <- as.data.frame(UCBAdmissions)
## Now 'DF' is a data frame with a grid of the factors and the counts
## in variable 'Freq'.
DF
## Nice for taking margins ...
xtabs(Freq ~ Gender + Admit, DF)
## And for testing independence ...
summary(xtabs(Freq ~ ., DF))

## with NA's
DN <- DF; DN[cbind(6:9, c(1:2,4,1))] <- NA
DN # 'Freq' is missing only for (Rejected, Female, B)
(xtNA <- xtabs(Freq ~ Gender + Admit, DN)) # NA prints 'invisibly'
print(xtNA, na.print = "NA") # show NA's better
xtabs(Freq ~ Gender + Admit, DN, na.rm = TRUE) # ignore missing Freq
## Use addNA = TRUE to tabulate missing factor levels:
xtabs(Freq ~ Gender + Admit, DN, addNA = TRUE)
xtabs(Freq ~ Gender + Admit, DN, addNA = TRUE, na.rm = TRUE)
## na.action = na.omit removes all rows with NAs right from the start:
xtabs(Freq ~ Gender + Admit, DN, na.action = na.omit)

## Create a nice display for the warp break data.
warpbreaks$replicate <- rep_len(1:9, 54)
ftable(xtabs(breaks ~ wool + tension + replicate, data = warpbreaks))

### ---- Sparse Examples ----

if(require("Matrix")) withAutoprint({
  ## similar to "nlme"s 'ergoStool' :
  d.ergo <- data.frame(Type = paste0("T", rep(1:4, 9*4)),
    Subj = gl(9, 4, 36*4))
  xtabs(~ Type + Subj, data = d.ergo) # 4 replicates each
```

```
set.seed(15) # a subset of cases:
xtabs(~ Type + Subj, data = d.ergo[sample(36, 10), ], sparse = TRUE)

## Hypothetical two-level setup:
inner <- factor(sample(letters[1:25], 100, replace = TRUE))
inout <- factor(sample(LETTERS[1:5], 25, replace = TRUE))
fr <- data.frame(inner = inner, outer = inout[as.integer(inner)])
xtabs(~ inner + outer, fr, sparse = TRUE)
})
```

# Chapter 11

## The stats4 package

---

stats4-package

*Statistical Functions using S4 Classes*

---

### Description

Statistical Functions using S4 classes.

### Details

This package contains functions and classes for statistics using the [S version 4](#) class system.

The methods currently support maximum likelihood (function `mle()` returning class "`mle`"), including methods for `logLik` for use with [AIC](#).

### Author(s)

R Core Team and contributors worldwide

Maintainer: R Core Team <[R-core@r-project.org](mailto:R-core@r-project.org)>

---

coef-methods

*Methods for Function `coef` in Package **stats4***

---

### Description

Extract the coefficient vector from "`mle`" objects.

### Methods

`signature(object = "ANY")` Generic function: see [coef](#).

`signature(object = "mle")` Extract the full coefficient vector (including any fixed coefficients) from the fit.

`signature(object = "summary.mle")` Extract the coefficient vector and standard errors from the summary of the fit.

---

|-----------------|-------------------------------------------------------|
| confint-methods | <i>Methods for Function confint in Package stats4</i> |
|-----------------|-------------------------------------------------------|

---

**Description**

Generate confidence intervals

**Methods**

signature(object = "ANY") Generic function: see [confint](#).

signature(object = "mle") First generate profile and then confidence intervals from the profile.

signature(object = "profile.mle") Generate confidence intervals based on likelihood profile.

---

|                |                                                      |
|----------------|------------------------------------------------------|
| logLik-methods | <i>Methods for Function logLik in Package stats4</i> |
|----------------|------------------------------------------------------|

---

**Description**

Extract the maximized log-likelihood from "mle" objects.

**Methods**

signature(object = "ANY") Generic function: see [logLik](#).

signature(object = "mle") Extract log-likelihood from the fit.

**Note**

The mle method does not know about the number of observations unless nobs was specified on the call and so may not be suitable for use with [BIC](#).

---

|     |                                      |
|-----|--------------------------------------|
| mle | <i>Maximum Likelihood Estimation</i> |
|-----|--------------------------------------|

---

**Description**

Estimate parameters by the method of maximum likelihood.

**Usage**

```
mle(minuslogl, start,
    optim = stats::optim,
    method = if(!useLim) "BFGS" else "L-BFGS-B",
    fixed = list(), nobs, lower, upper, ...)
```

## Arguments

|                           |                                                                                                                                             |
|---------------------------|---------------------------------------------------------------------------------------------------------------------------------------------|
| <code>minuslogl</code>    | Function to calculate negative log-likelihood.                                                                                              |
| <code>start</code>        | Named list of vectors or single vector. Initial values for optimizer. By default taken from the default arguments of <code>minuslogl</code> |
| <code>optim</code>        | Optimizer function. (Experimental)                                                                                                          |
| <code>method</code>       | Optimization method to use. See <a href="#">optim</a> .                                                                                     |
| <code>fixed</code>        | Named list of vectors or single vector. Parameter values to keep fixed during optimization.                                                 |
| <code>nobs</code>         | optional integer: the number of observations, to be used for e.g. computing <a href="#">BIC</a> .                                           |
| <code>lower, upper</code> | Named lists of vectors or single vectors. Bounds for <a href="#">optim</a> , if relevant.                                                   |
| <code>...</code>          | Further arguments to pass to <a href="#">optim</a> .                                                                                        |

## Details

The `optim` optimizer is used to find the minimum of the negative log-likelihood. An approximate covariance matrix for the parameters is obtained by inverting the Hessian matrix at the optimum. By default, [optim](#) from the `stats` package is used; other optimizers need to be plug-compatible, both with respect to arguments and return values.

The function `minuslogl` should take one or several arguments, each of which can be a vector. The optimizer optimizes a function which takes a single vector argument, containing the concatenation of the arguments to `minuslogl`, removing any values that should be held fixed. This function internally unpacks the argument vector, inserts the fixed values and calls `minuslogl`.

The vector arguments `start`, `fixed`, `upper`, and `lower`, can be given in both packed and unpacked form, either as a single vector or as a list of vectors. In the latter case, you only need to specify those list elements that are actually affected. For vector arguments, including those inside lists, use a default marker for those values that you don't want to set: `NA` for `fixed` and `start`, and `+Inf`, `-Inf` for `upper`, and `lower`.

## Value

An object of class [mle-class](#).

## Note

Notice that the `mll` argument should calculate  $-\log L$  (not  $-2 \log L$ ). It is for the user to ensure that the likelihood is correct, and that asymptotic likelihood inference is valid.

## See Also

[mle-class](#)

## Examples

```
## Avoid printing to unwarranted accuracy
od <- options(digits = 5)

## Simulated EC50 experiment with count data
x <- 0:10
y <- c(26, 17, 13, 12, 20, 5, 9, 8, 5, 4, 8)

## Easy one-dimensional MLE:
```

```

nLL <- function(lambda) -sum(stats::dpois(y, lambda, log = TRUE))
fit0 <- mle(nLL, start = list(lambda = 5), nobs = NROW(y))

## sanity check --- notice that "nobs" must be input
## (not guaranteed to be meaningful for any likelihood)
stopifnot(nobs(fit0) == length(y))

# For 1D, this is preferable:
fit1 <- mle(nLL, start = list(lambda = 5), nobs = NROW(y),
           method = "Brent", lower = 1, upper = 20)

## This needs a constrained parameter space: most methods will accept NA
ll <- function(ymax = 15, xhalf = 6) {
  if(ymax > 0 && xhalf > 0)
    -sum(stats::dpois(y, lambda = ymax/(1+x/xhalf), log = TRUE))
  else NA
}
(fit <- mle(ll, nobs = length(y)))
mle(ll, fixed = list(xhalf = 6))

## Alternative using bounds on optimization
ll2 <- function(ymax = 15, xhalf = 6)
  -sum(stats::dpois(y, lambda = ymax/(1+x/xhalf), log = TRUE))
mle(ll2, lower = rep(0, 2))

AIC(fit)
BIC(fit)

summary(fit)
logLik(fit)
vcov(fit)
plot(profile(fit), absVal = FALSE)
confint(fit)

## Use bounded optimization
## The lower bounds are really > 0,
## but we use >=0 to stress-test profiling
(fit2 <- mle(ll2, lower = c(0, 0)))
plot(profile(fit2), absVal = FALSE)

## A better parametrization:
ll3 <- function(lymax = log(15), lxhalf = log(6))
  -sum(stats::dpois(y, lambda = exp(lymax)/(1+x/exp(lxhalf)), log = TRUE))
(fit3 <- mle(ll3))
plot(profile(fit3), absVal = FALSE)
exp(confint(fit3))

# Regression tests for bounded cases (this was broken in R 3.x)
fit4 <- mle(ll, lower = c(0, 4)) # has max on boundary
confint(fit4)

## direct check that fixed= and constraints work together
mle(ll, lower = c(0, 4), fixed=list(ymax=23)) # has max on boundary

## Linear regression using MLE
x <- 1:10

```

```

y <- c(0.48, 2.24, 2.22, 5.15, 4.64, 5.53, 7, 8.8, 7.67, 9.23)

LM_mll <- function(formula, data = environment(formula))
{
  y <- model.response(model.frame(formula, data))
  X <- model.matrix(formula, data)
  b0 <- numeric(NCOL(X))
  names(b0) <- colnames(X)
  function(b=b0, sigma=1)
    -sum(dnorm(y, X %*% b, sigma, log=TRUE))
}

mll <- LM_mll(y ~ x)

summary(lm(y~x)) # for comparison -- notice variance bias in MLE
summary(mle(mll, lower=c(-Inf,-Inf, 0.01)))
summary(mle(mll, lower=list(sigma = 0.01))) # alternative specification

confint(mle(mll, lower=list(sigma = 0.01)))
plot(profile(mle(mll, lower=list(sigma = 0.01))))

Binom_mll <- function(x, n)
{
  force(x); force(n) ## beware lazy evaluation
  function(p=.5) -dbinom(x, n, p, log=TRUE)
}

## Likelihood functions for different x.
## This code goes wrong, if force(x) is not used in Binom_mll:

curve(Binom_mll(0, 10)(p), xname="p", ylim=c(0, 10))
mll_list <- list(10)
for (x in 1:10)
  mll_list[[x]] <- Binom_mll(x, 10)
for (mll in mll_list)
  curve(mll(p), xname="p", add=TRUE)

mll <- Binom_mll(4,10)
mle(mll, lower = 1e-16, upper = 1-1e-16) # limits must be inside (0,1)

## Boundary case: This works, but fails if limits are set closer to 0 and 1
mll <- Binom_mll(0, 10)
mle(mll, lower=.005, upper=.995)

## Not run:
## We can use limits closer to the boundaries if we use the
## drop-in replacement optimr() from the optimx package.

mle(mll, lower = 1e-16, upper = 1-1e-16, optim=optimx::optimr)

## End(Not run)

```

mle-class

*Class "mle" for Results of Maximum Likelihood Estimation***Description**

This class encapsulates results of a generic maximum likelihood procedure.

**Objects from the Class**

Objects can be created by calls of the form `new("mle", ...)`, but most often as the result of a call to `mle`.

**Slots**

**call**: Object of class "language". The call to `mle`.

**coef**: Object of class "numeric". Estimated parameters.

**fullcoef**: Object of class "numeric". Full parameter set of fixed and estimated parameters.

**fixed**: Object of class "numeric". Fixed parameter values (NA for non-fixed parameters).

**vcov**: Object of class "matrix". Approximate variance-covariance matrix.

**min**: Object of class "numeric". Minimum value of objective function.

**details**: a "list", as returned from `optim`.

**minuslogl**: Object of class "function". The negative loglikelihood function.

**nobs**: "integer" of length one. The number of observations (often NA, when not set in call explicitly).

**method**: Object of class "character". The optimization method used.

**Methods**

**confint** signature(object = "mle"): Confidence intervals from likelihood profiles.

**logLik** signature(object = "mle"): Extract maximized log-likelihood.

**profile** signature(fitted = "mle"): Likelihood profile generation.

**nobs** signature(object = "mle"): Number of observations, here simply accessing the nobs slot mentioned above.

**show** signature(object = "mle"): Display object briefly.

**summary** signature(object = "mle"): Generate object summary.

**update** signature(object = "mle"): Update fit.

**vcov** signature(object = "mle"): Extract variance-covariance matrix.

plot-methods

*Methods for Function plot in Package stats4***Description**

Plot profile likelihoods for "mle" objects.

**Usage**

```
## S4 method for signature 'profile.mle,missing'
plot(x, levels, conf = c(99, 95, 90, 80, 50)/100, nseg = 50,
     absVal = TRUE, ...)
```

**Arguments**

|        |                                                                                                                                                           |
|--------|-----------------------------------------------------------------------------------------------------------------------------------------------------------|
| x      | an object of class "profile.mle"                                                                                                                          |
| levels | levels, on the scale of the absolute value of a t statistic, at which to interpolate intervals. Usually conf is used instead of giving levels explicitly. |
| conf   | a numeric vector of confidence levels for profile-based confidence intervals on the parameters.                                                           |
| nseg   | an integer value giving the number of segments to use in the spline interpolation of the profile t curves.                                                |
| absVal | a logical value indicating whether or not the plots should be on the scale of the absolute value of the profile t. Defaults to TRUE.                      |
| ...    | other arguments to the plot function can be passed here.                                                                                                  |

**Methods**

signature(x = "ANY", y = "ANY") Generic function: see [plot](#).

signature(x = "profile.mle", y = "missing") Plot likelihood profiles for x.

profile-methods

*Methods for Function profile in Package stats4***Description**

Profile likelihood for "mle" objects.

**Usage**

```
## S4 method for signature 'mle'
profile(fitted, which = 1:p, maxsteps = 100, alpha = 0.01,
       zmax = sqrt(qchisq(1 - alpha, 1L)), del = zmax/5,
       trace = FALSE, ...)
```

**Arguments**

|          |                                                                                                                             |
|----------|-----------------------------------------------------------------------------------------------------------------------------|
| fitted   | Object to be profiled                                                                                                       |
| which    | Optionally select subset of parameters to profile.                                                                          |
| maxsteps | Maximum number of steps to bracket zmax.                                                                                    |
| alpha    | Significance level corresponding to zmax, based on a Scheffe-style multiple testing interval. Ignored if zmax is specified. |
| zmax     | Cutoff for the profiled value of the signed root-likelihood.                                                                |
| del      | Initial stepsize on root-likelihood scale.                                                                                  |
| trace    | Logical. Print intermediate results.                                                                                        |
| ...      | Currently unused.                                                                                                           |

**Details**

The profiling algorithm tries to find an approximately evenly spaced set of at least five parameter values (in each direction from the optimum) to cover the root-likelihood function. Some care is taken to try and get sensible results in cases of high parameter curvature. Notice that it may not always be possible to obtain the cutoff value, since the likelihood might level off.

**Value**

An object of class "profile.mle", see "profile.mle-class".

**Methods**

signature(fitted = "ANY") Generic function: see [profile](#).

signature(fitted = "mle") Profile the likelihood in the vicinity of the optimum of an "mle" object.

---

|                   |                                                                    |
|-------------------|--------------------------------------------------------------------|
| profile.mle-class | <i>Class "profile.mle"; Profiling information for "mle" object</i> |
|-------------------|--------------------------------------------------------------------|

---

**Description**

Likelihood profiles along each parameter of likelihood function

**Objects from the Class**

Objects can be created by calls of the form `new("profile.mle", ...)`, but most often by invoking `profile` on an "mle" object.

**Slots**

**profile:** Object of class "list". List of profiles, one for each requested parameter. Each profile is a data frame with the first column called `z` being the signed square root of the  $-2 \log$  likelihood ratio, and the others being the parameters with names prefixed by `par.vals`.

**summary:** Object of class "summary.mle". Summary of object being profiled.

Methods

- confint** signature(object = "profile.mle"): Use profile to generate approximate confidence intervals for parameters.
- plot** signature(x = "profile.mle", y = "missing"): Plot profiles for each parameter.

| summary-methods | <i>Methods for Function summary in Package stats4</i> |
|-----------------|-------------------------------------------------------|

---

Description

Summarize objects

Methods

- signature(object = "ANY") Generic function
- signature(object = "mle") Generate a summary as an object of class "summary.mle", containing estimates, asymptotic SE, and value of  $-2 \log L$ .

---

|                   |                                                      |
|-------------------|------------------------------------------------------|
| summary.mle-class | <i>Class "summary.mle", Summary of "mle" Objects</i> |
|-------------------|------------------------------------------------------|

---

**Description**

Extract of "mle" object

**Objects from the Class**

Objects can be created by calls of the form `new("summary.mle", ...)`, but most often by invoking `summary` on an "mle" object. They contain values meant for printing by `show`.

**Slots**

- `call`: Object of class "language" The call that generated the "mle" object.
- `coef`: Object of class "matrix". Estimated coefficients and standard errors
- `m2logL`: Object of class "numeric". Minus twice the log likelihood.

**Methods**

- `show` signature(object = "summary.mle"): Pretty-prints object
- `coef` signature(object = "summary.mle"): Extracts the contents of the `coef` slot

|----------------|------------------------------------------------------|
| update-methods | <i>Methods for Function update in Package stats4</i> |
|----------------|------------------------------------------------------|

---

**Description**

Update "mle" objects.

**Usage**

```
## S4 method for signature 'mle'
update(object, ..., evaluate = TRUE)
```

**Arguments**

- `object` An existing fit.
- `...` Additional arguments to the call, or arguments with changed values. Use `name = NULL` to remove the argument name.
- `evaluate` If true evaluate the new call else return the call.

**Methods**

`signature(object = "ANY")` Generic function: see [update](#).

`signature(object = "mle")` Update a fit.

**Examples**

```
x <- 0:10
y <- c(26, 17, 13, 12, 20, 5, 9, 8, 5, 4, 8)
ll <- function(ymax = 15, xhalf = 6)
  -sum(stats::dpois(y, lambda = ymax/(1+x/xhalf), log = TRUE))
fit <- mle(ll)
## note the recorded call contains ..1, a problem with S4 dispatch
update(fit, fixed = list(xhalf = 3))
```

---

vcov-methods

*Methods for Function vcov in Package stats4*

---

**Description**

Extract the approximate variance-covariance matrix from "mle" objects.

**Methods**

`signature(object = "ANY")` Generic function: see [vcov](#).

`signature(object = "mle")` Extract the estimated variance-covariance matrix for the estimated parameters (if any).

## Chapter 12

# The tcltk package

---

tcltk-package

*Tcl/Tk Interface*

---

### Description

Interface and language bindings to Tcl/Tk GUI elements.

### Details

This package provides access to the platform-independent Tcl scripting language and Tk GUI elements. See [TkWidgets](#) for a list of supported widgets, [TkWidgetcmds](#) for commands to work with them, and references in those files for more.

The Tcl/Tk documentation is in the system man pages.

For a complete list of functions, use `ls("package:tcltk")`.

Note that Tk will not be initialized if there is no `DISPLAY` variable set, but Tcl can still be used. This is most useful to allow the loading of a package which depends on **tcltk** in a session that does not actually use it (e.g., during installation).

### Author(s)

R Core Team

Maintainer: R Core Team <R-core@r-project.org>

---

TclInterface

*Low-level Tcl/Tk Interface*

---

### Description

These functions and variables provide the basic glue between R and the Tcl interpreter and Tk GUI toolkit. Tk windows may be represented via R objects. Tcl variables can be accessed via objects of class `tclVar` and the C level interface to Tcl objects is accessed via objects of class `tclObj`.

**Usage**

```

.Tcl(...)
.Tcl.objv(objv)
.Tcl.args(...)
.Tcl.args.objv(...)
.Tcl.callback(...)
.Tk.ID(win)
.Tk.newwin(ID)
.Tk.subwin(parent)
.TkRoot
.TkUp

tkdestroy(win)
is.tkwin(x)

tclvalue(x)
tclvalue(x) <- value

tclVar(init = "")
## S3 method for class 'tclVar'
as.character(x, ...)
## S3 method for class 'tclVar'
tclvalue(x)
## S3 replacement method for class 'tclVar'
tclvalue(x) <- value

tclArray()
## S3 method for class 'tclArray'
x[[...]]
## S3 replacement method for class 'tclArray'
x[[...]] <- value
## S3 method for class 'tclArray'
x$i
## S3 replacement method for class 'tclArray'
x$i <- value

## S3 method for class 'tclArray'
names(x)
## S3 method for class 'tclArray'
length(x)

tclObj(x)
tclObj(x) <- value
## S3 method for class 'tclVar'
tclObj(x)
## S3 replacement method for class 'tclVar'
tclObj(x) <- value

as.tclObj(x, drop = FALSE)
is.tclObj(x)

## S3 method for class 'tclObj'

```

```

as.character(x, ...)
## S3 method for class 'tclObj'
as.integer(x, ...)
## S3 method for class 'tclObj'
as.double(x, ...)
## S3 method for class 'tclObj'
as.logical(x, ...)
## S3 method for class 'tclObj'
as.raw(x, ...)
## S3 method for class 'tclObj'
tclvalue(x)

## Default S3 method:
tclvalue(x)
## Default S3 replacement method:
tclvalue(x) <- value

addTclPath(path = ".")
tclRequire(package, warn = TRUE)
tclVersion(with_patchlevel = FALSE)

```

### Arguments

|                 |                                                                                                                    |
|-----------------|--------------------------------------------------------------------------------------------------------------------|
| objv            | a named vector of Tcl objects                                                                                      |
| win             | a window structure                                                                                                 |
| x               | an object                                                                                                          |
| i               | character or (unquoted) name                                                                                       |
| drop            | logical. Indicates whether a single-element vector should be made into a simple Tcl object or a list of length one |
| value           | For tclvalue assignments, a character string. For tclObj assignments, an object of class tclObj                    |
| ID              | a window ID                                                                                                        |
| parent          | a window which becomes the parent of the resulting window                                                          |
| path            | path to a directory containing Tcl packages                                                                        |
| package         | a Tcl package name                                                                                                 |
| warn            | logical. Warn if not found?                                                                                        |
| ...             | Additional arguments. See below.                                                                                   |
| init            | initialization value                                                                                               |
| with_patchlevel | logical: should the 'patch level' be included?                                                                     |

### Details

Many of these functions are not intended for general use but are used internally by the commands that create and manipulate Tk widgets and Tcl objects. At the lowest level `.Tcl` sends a command as a text string to the Tcl interpreter and returns the result as an object of class `tclObj` (see below). A newer variant `.Tcl.objv` accepts arguments in the form of a named list of `tclObj` objects.

`.Tcl.args` converts an R argument list of `tag = value` pairs to the Tcl `-option value` style, thus enabling a simple translation between the two languages. To send a value with no preceding option flag to Tcl, just use an untagged argument. In the rare case one needs an option with no subsequent value `tag = NULL` can be used. Most values are just converted to character mode and inserted in the command string, but window objects are passed using their ID string, and callbacks are passed via the result of `.Tcl.callback`. Tags are converted to option flags simply by prepending a `'-'`.

`.Tcl.args.objv` serves a similar purpose as `.Tcl.args` but produces a list of `tclObj` objects suitable for passing to `.Tcl.objv`. The names of the list are converted to Tcl option style internally by `.Tcl.objv`.

Callbacks can be either *atomic callbacks* handled by `.Tcl.callback` or expressions. An expression is treated as a list of atomic callbacks, with the following exceptions: if an element is a name, it is first evaluated in the callers frame, and likewise if it is an explicit function definition; the `break` expression is translated directly to the Tcl counterpart. `.Tcl.callback` converts R functions and unevaluated calls to Tcl command strings. The argument must be either a function closure or an object of mode `"call"` followed by an environment. The return value in the first case is of the form `R_call 0x408b94d4` in which the hexadecimal number is the memory address of the function. In the second case it will be of the form `R_call_lang 0x8a95904 0x819bfd0`. For expressions, a sequence of similar items is generated, separated by semicolons. `.Tcl.args` takes special precautions to ensure that functions or calls will continue to exist at the specified address by assigning the callback into the relevant window environment (see below).

Tk windows are represented as objects of class `tkwin` which are lists containing a `ID` field and an `env` field which is an R environments, enclosed in the global environment. The value of the `ID` field is identical to the Tk window name. The `env` environment contains a `parent` variable and a `num.subwin` variable. If the window obtains sub-windows and callbacks, they are added as variables to the environment. `.TkRoot` is the top window with ID `"."`; this window is not displayed in order to avoid ill effects of closing it via window manager controls. The `parent` variable is undefined for `.TkRoot`.

`.Tk.ID` extracts the ID of a window, `.Tk.newwin` creates a new window environment with a given ID and `.Tk.subwin` creates a new window which is a sub-window of a given parent window.

`.TkUp` is a logical flag to indicate whether the Tk widget system is active; if `FALSE`, only the Tcl interpreter is available.

`tkdestroy` destroys a window and also removes the reference to a window from its parent.

`is.tkwin` can be used to test whether a given object is a window environment.

`tclVar` creates a new Tcl variable and initializes it to `init`. An R object of class `tclVar` is created to represent it. Using `as.character` on the object returns the Tcl variable name. Accessing the Tcl variable from R is done using the `tclvalue` function, which can also occur on the left-hand side of assignments. If `tclvalue` is passed an argument which is not a `tclVar` object, then it will assume that it is a character string explicitly naming global Tcl variable. Tcl variables created by `tclVar` are uniquely named and automatically unset by the garbage collector when the representing object is no longer in use.

`tclArray` creates a new Tcl array and initializes it to the empty array. An R object of class `tclArray` and inheriting from class `tclVar` is created to represent it. You can access elements of the Tcl array using indexing with `[]` or `$`, which also allow replacement forms. Notice that Tcl arrays are associative by nature and hence unordered; indexing with a numeric index `i` refers to the element with the *name* `as.character(i)`. Multiple indices are pasted together separated by commas to form a single name. You can query the length and the set of names in an array using methods for `length` and `names`, respectively; these cannot meaningfully be set so assignment forms exist only to print an error message.

It is possible to access Tcl's 'dual-ported' objects directly, thus avoiding parsing and deparsing of their string representation. This works by using objects of class `tclObj`. The string representation

of such objects can be extracted (but not set) using `tclvalue` and conversion to vectors of mode "character", "double", "integer", "logical", and "raw" is performed using the standard coercion functions `as.character`, etc. Conversely, such vectors can be converted using `as.tclobj`. There is an ambiguity as to what should happen for length one vectors, controlled by the `drop` argument; there are cases where the distinction matters to Tcl, although mostly it treats them equivalently. Notice that `tclvalue` and `as.character` differ on an object whose string representation has embedded spaces, the former is sometimes to be preferred, in particular when applied to the result of `tclread`, `tkgetOpenFile`, and similar functions. The `as.raw` method returns a raw vector or a list of raw vectors and can be used to return binary data from Tcl.

The object behind a `tclVar` object is extracted using `tclobj(x)` which also allows an assignment form, in which the right hand side of the assignment is automatically converted using `as.tclobj`. There is a print method for `tclobj` objects; it prints '<Tcl>' followed by the string representation of the object. Notice that `as.character` on a `tclVar` object is the *name* of the corresponding Tcl variable and not the value.

Tcl packages can be loaded with `tclRequire`; it may be necessary to add the directory where they are found to the Tcl search path with `addTclPath`. The return value is a class "tclobj" object if it succeeds, or FALSE if it fails (when a warning is issued unless `warn` is false). To see the current search path as an R character vector, use:

```
strsplit(tclvalue('auto_path'), " ")[[1]]
```

Note that a report of 'not found' will be given if the package is found but is not compatible with the Tcl/Tk version in use.

`tclVersion` optionally returns the full Tcl version as a character string such as "8.6.16" or "9.0.1". NB: the 'patch level' is not necessarily numeric, e.g. for version 9.0b1. (R versions before 4.6.0 reported the full version including the 'patch level'.)

### Note

Strings containing unbalanced braces are currently not handled well in many circumstances.

### See Also

[TkWidgets](#), [TkCommands](#), [TkWidgetcmds](#).

`capabilities("tcltk")` to see if Tcl/Tk support was compiled into this build of R.

### Examples

```
tclVersion()
tclVersion(TRUE)

.Tcl("format \"%s\n\" \"Hello, World!\")

f <- function() cat("HI!\n")
.Tcl.callback(f)
.Tcl.args(text = "Push!", command = f) # NB: Different address

xyzy <- tclVar(7913)
tclvalue(xyzy)
tclvalue(xyzy) <- "foo"
as.character(xyzy)
tcl("set", as.character(xyzy))
```

```
## Not run:
## These cannot be run by example() but should be OK when pasted
## into an interactive R session with the tcltk package loaded
top <- tktoplevel() # a Tk widget, see ?Tkwidgets
ls(envir = top$env, all.names = TRUE)

## End(Not run)

ls(envir = .TkRoot$env, all.names = TRUE) # .Tcl.args put a callback ref in here
```

---

|                |                                               |
|----------------|-----------------------------------------------|
| tclServiceMode | <i>Allow Tcl events to be serviced or not</i> |
|----------------|-----------------------------------------------|

---

## Description

This function controls or reports on the Tcl service mode, i.e., whether Tcl will respond to events.

## Usage

```
tclServiceMode(on = NULL)
```

## Arguments

on (logical) Whether event servicing is turned on.

## Details

If called with on == NULL (the default), no change is made.

Note that this blocks all Tcl/Tk activity, including for widgets from other packages. It may be better to manage mapping of windows individually.

## Value

The value of the Tcl service mode before the call.

## Examples

```
## see demo(tkcanvas) for an example
oldmode <- tclServiceMode(FALSE)
# Do some work to create a nice picture.
# Nothing will be displayed until...
tclServiceMode(oldmode)
## another idea is to use tkwm.withdraw() ... tkwm.deiconify()
```

---

TkCommands

*Tk non-widget commands*

---

## Description

These functions interface to Tk non-widget commands, such as the window manager interface commands and the geometry managers.

## Usage

```
tcl(...)
tktitle(x)

tktitle(x) <- value

tkbell(...)
tkbind(...)
tkbindtags(...)
tkfocus(...)
tklower(...)
tkraise(...)

tkclipboard.append(...)

### Arguments

|       |                                               |
|-------|-----------------------------------------------|
| x     | A window object                               |
| value | For ttktitle assignments, a character string. |
| ...   | Handled via <code>.Tcl.args</code>            |

## Details

tcl provides a generic interface to calling any Tk or Tcl command by simply running `.Tcl.args.objv` on the argument list and passing the result to `.Tcl.objv`. Most of the other commands simply call `tcl` with a particular first argument and sometimes also a second argument giving the subcommand.

`tktitle` and its assignment form provides an alternate interface to Tk's `wm title`

There are far too many of these commands to describe them and their arguments in full. Please refer to the Tcl/Tk documentation for details. With a few exceptions, the pattern is that Tk subcommands like `pack` `configure` are converted to function names like `tkpack.configure`, and Tcl subcommands are like `tclfile.dir`.

## See Also

[TclInterface](#), [TkWidgets](#), [TkWidgetcmds](#)

## Examples

```
## Not run:
## These cannot be run by examples() but should be OK when pasted
## into an interactive R session with the tcltk package loaded

tt <- tktoplevel()
tkpack(l1 <- tclabel(tt, text = "Heave"), l2 <- tclabel(tt, text = "Ho"))
tkpack.configure(l1, side = "left")

## Try stretching the window and then

tkdestroy(tt)

## End(Not run)
```

---

tkpager

*Page file using Tk text widget*

---

## Description

This plugs into `file.show`, showing files in separate windows.

## Usage

```
tkpager(file, header, title, delete.file)
```

## Arguments

|                          |                                                                                                     |
|--------------------------|-----------------------------------------------------------------------------------------------------|
| <code>file</code>        | character vector containing the names of the files to be displayed                                  |
| <code>header</code>      | headers to use for each file                                                                        |
| <code>title</code>       | common title to use for the window(s). Pasted together with the header to form actual window title. |
| <code>delete.file</code> | logical. Should file(s) be deleted after display?                                                   |

**Note**

The "\b\_" string used for underlining is currently quietly removed. The font and background colour are currently hardcoded to Courier and gray90.

**See Also**

[file.show](#)

---

|               |                             |
|---------------|-----------------------------|
| tkProgressBar | <i>Progress Bars via Tk</i> |
|---------------|-----------------------------|

---

**Description**

Put up a Tk progress bar widget.

**Usage**

```
tkProgressBar(title = "R progress bar", label = "",
              min = 0, max = 1, initial = 0, width = 300)

getTkProgressBar(pb)
setTkProgressBar(pb, value, title = NULL, label = NULL)
## S3 method for class 'tkProgressBar'
close(con, ...)
```

**Arguments**

|                |                                                                                               |
|----------------|-----------------------------------------------------------------------------------------------|
| title, label   | character strings, giving the window title and the label on the dialog box respectively.      |
| min, max       | (finite) numeric values for the extremes of the progress bar.                                 |
| initial, value | initial or new value for the progress bar.                                                    |
| width          | the width of the progress bar in pixels: the dialog box will be 40 pixels wider (plus frame). |
| pb, con        | an object of class "tkProgressBar".                                                           |
| ...            | for consistency with the generic.                                                             |

**Details**

tkProgressBar will display a widget containing a label and progress bar.

setTkProgressBar will update the value and for non-NULL values, the title and label (provided there was one when the widget was created). Missing (NA) and out-of-range values of value will be (silently) ignored.

The progress bar should be closed when finished with.

This will use the ttk::progressbar widget for Tk version 8.5 or later, otherwise R's copy of BWidget's progressbar.

**Value**

For tkProgressBar an object of class "tkProgressBar".

For getTkProgressBar and setTkProgressBar, a length-one numeric vector giving the previous value (invisibly for setTkProgressBar).

**See Also**

[txtProgressBar](#)

**Examples**

```
pb <- tkProgressBar("test progress bar", "Some information in %",
                    0, 100, 50)
Sys.sleep(0.5)
u <- c(0, sort(runif(20, 0, 100)), 100)
for(i in u) {
  Sys.sleep(0.1)
  info <- sprintf("%d%% done", round(i))
  setTkProgressBar(pb, i, sprintf("test (%s)", info), info)
}
Sys.sleep(5)
close(pb)
```

---

tkStartGUI

*Tcl/Tk GUI startup*

---

**Description**

Starts up the Tcl/Tk GUI

**Usage**

```
tkStartGUI()
```

**Details**

Starts a GUI console implemented via a Tk text widget. This should probably be called at most once per session. Also redefines the file pager (as used by `help()`) to be the Tk pager.

**Note**

tkStartGUI() saves its evaluation environment as `.GUIenv`. This means that the user interface elements can be accessed in order to extend the interface. The three main objects are named `Term`, `Menu`, and `Toolbar`, and the various submenus and callback functions can be seen with `ls(envir = .GUIenv)`.

tkinsert(txt.w, "0.0", "plot(1:10)")

# callback function
eval.txt <- function() eval(str2lang(tclvalue(tkget(txt.w, "0.0", "end"))))
tkpack(but.w <- tkbutton(tt, text = "Submit", command = eval.txt))

## Try pressing the button, edit the text and when finished:

tkdestroy(tt)

## End(Not run)
```

---

TkWidgets

*Tk widgets*

---

**Description**

Create Tk widgets and associated R objects.

**Usage**

```
tkwidget(parent, type, ...)

tkbutton(parent, ...)
tkcanvas(parent, ...)
tkcheckboxbutton(parent, ...)
tkentry(parent, ...)
ttkentry(parent, ...)
```

```
tkframe(parent, ...)
tklabel(parent, ...)
tklistbox(parent, ...)
tkmenu(parent, ...)
tkmenubutton(parent, ...)
tkmessage(parent, ...)
tkradiobutton(parent, ...)
tkscale(parent, ...)
tkscrollbar(parent, ...)
tktext(parent, ...)
tktoplevel(parent = .TkRoot, ...)
```

```
ttkbutton(parent, ...)
ttkcheckbutton(parent, ...)
ttkcombobox(parent, ...)
ttkframe(parent, ...)
ttklabel(parent, ...)
ttklabelframe(parent, ...)
ttkmenubutton(parent, ...)
ttknotebook(parent, ...)
ttkpanedwindow(parent, ...)
ttkprogressbar(parent, ...)
ttkradiobutton(parent, ...)
ttkscale(parent, ...)
ttkscrollbar(parent, ...)
ttkseparator(parent, ...)
ttksizegrip(parent, ...)
ttkspinbox(parent, ...)
ttktreeview(parent, ...)
```

### Arguments

|        |                                               |
|--------|-----------------------------------------------|
| parent | Parent of widget window.                      |
| type   | string describing the type of widget desired. |
| ...    | handled via <a href="#">.Tcl.args</a> .       |

### Details

These functions create Tk widgets. `tkwidget` creates a widget of a given type, the others simply call `tkwidget` with the respective type argument.

The functions starting `ttk` are for the themed widget set for Tk 8.5 or later. A tutorial can be found at <https://tkdocs.com/>.

It is not possible to describe the widgets and their arguments in full. Please refer to the Tcl/Tk documentation.

### Examples

```
## Not run:
```

```

## These cannot be run by examples() but should be OK when pasted
## into an interactive R session with the tcltk package loaded

tt <- tktoplevel()
label.widget <- tklabel(tt, text = "Hello, World!")
button.widget <- tkbutton(tt, text = "Push",
                          command = function()cat("OW!\n"))
tkpack(label.widget, button.widget) # geometry manager
                                   # see Tk-commands

## Push the button and then...

tkdestroy(tt)

## test for themed widgets
if(as.character(tcl("info", "tclversion")) >= "8.5") {
  # make use of themed widgets
  # list themes
  themes <- as.character(tcl("ttk::style", "theme", "names"))
  themes
  # select a theme -- for pre-XP windows
  # tcl("ttk::style", "theme", "use", "winnative")
  tcl("ttk::style", "theme", "use", themes[1])
} else {
  # use Tk 8.0 widgets
}

## End(Not run)

```

tk\_choose.dir

*Choose a Folder Interactively***Description**

Use a Tk widget to choose a directory interactively.

**Usage**

```
tk_choose.dir(default = "", caption = "Select directory")
```

**Arguments**

|         |                                      |
|---------|--------------------------------------|
| default | which directory to show initially.   |
| caption | the caption on the selection dialog. |

**Value**

A length-one character vector, character NA if 'Cancel' was selected.

**See Also**

[tk\\_choose.files](#)

**Examples**

```
if (interactive()) tk_choose.dir(getwd(), "Choose a suitable folder")
```

---

|                 |                                             |
|-----------------|---------------------------------------------|
| tk_choose.files | <i>Choose a List of Files Interactively</i> |
|-----------------|---------------------------------------------|

---

**Description**

Use a Tk file dialog to choose a list of zero or more files interactively.

**Usage**

```
tk_choose.files(default = "", caption = "Select files",
                multi = TRUE, filters = NULL, index = 1)
```

**Arguments**

|         |                                                  |
|---------|--------------------------------------------------|
| default | which filename to show initially.                |
| caption | the caption on the file selection dialog.        |
| multi   | whether to allow multiple files to be selected.  |
| filters | two-column character matrix of filename filters. |
| index   | unused.                                          |

**Details**

Unlike [file.choose](#), `tk_choose.files` will always attempt to return a character vector giving a list of files. If the user cancels the dialog, then zero files are returned, whereas [file.choose](#) would signal an error.

The format of `filters` can be seen from the example. File patterns are specified via extensions, with "\*" meaning any file, and "" any file without an extension (a filename not containing a period). (Other forms may work on specific platforms.) Note that the way to have multiple extensions for one file type is to have multiple rows with the same name in the first column, and that whether the extensions are named in file chooser widget is platform-specific. **The format may change before release.**

**Value**

A character vector giving zero or more file paths.

**Note**

A bug in Tk 8.5.0–8.5.4 prevented multiple selections being used.

**See Also**

[file.choose](#), [tk\\_choose.dir](#)

**Examples**

```
Filters <- matrix(c("R code", ".R", "R code", ".s",  
                  "Text", ".txt", "All files", "*"),  
                4, 2, byrow = TRUE)  
  
Filters  
if(interactive()) tk_choose.files(filter = Filters)
```

---

tk\_messageBox

*Tk Message Box*

---

**Description**

An implementation of a generic message box using Tk.

**Usage**

```
tk_messageBox(type = c("ok", "okcancel", "yesno", "yesnocancel",  
                      "retrycancel", "abortretryignore"),  
             message, caption = "", default = "", ...)
```

**Arguments**

|         |                                                                                                          |
|---------|----------------------------------------------------------------------------------------------------------|
| type    | character. The type of dialog box. It will have the buttons implied by its name. Can be abbreviated.     |
| message | character. The information field of the dialog box.                                                      |
| caption | the caption on the widget displayed.                                                                     |
| default | character. The name of the button to be used as the default.                                             |
| ...     | additional named arguments to be passed to the Tk function of this name. An example is icon = "warning". |

**Value**

A character string giving the name of the button pressed.

**See Also**

[tkmessageBox](#) for a 'raw' interface.

---

|                |                          |
|----------------|--------------------------|
| tk_select.list | Select Items from a List |
|----------------|--------------------------|

---

### Description

Select item(s) from a character vector using a Tk listbox.

### Usage

```
tk_select.list(choices, preselect = NULL, multiple = FALSE,  
              title = NULL)
```

### Arguments

|           |                                                                                                                       |
|-----------|-----------------------------------------------------------------------------------------------------------------------|
| choices   | a character vector of items.                                                                                          |
| preselect | a character vector, or NULL. If non-null and if the string(s) appear in the list, the item(s) are selected initially. |
| multiple  | logical: can more than one item be selected?                                                                          |
| title     | optional character string for window title, or NULL for no title.                                                     |

### Details

This is a version of [select.list](#) implemented as a Tk list box plus OK and Cancel buttons. There will be a scrollbar if the list is too long to fit comfortably on the screen.

The dialog box is *modal*, so a selection must be made or cancelled before the R session can proceed. Double-clicking on an item is equivalent to selecting it and then clicking OK.

If Tk is version 8.5 or later, themed widgets will be used.

### Value

A character vector of selected items. If `multiple` is false and no item was selected (or Cancel was used), "" is returned. If `multiple` is true and no item was selected (or Cancel was used) then a character vector of length 0 is returned.

### See Also

[select.list](#) (a text version except on Windows and the macOS GUI), [menu](#) (whose `graphics = TRUE` mode uses this on most Unix-alikes).

## Chapter 13

# The tools package

---

tools-package

*Tools for Package Development*

---

### Description

Tools for package development, administration and documentation.

### Details

This package contains tools for manipulating R packages and their documentation.

For a complete list of functions, use `library(help = "tools")`.

### Author(s)

Kurt Hornik and Friedrich Leisch

Maintainer: R Core Team <R-core@r-project.org>

---

.print.via.format

*Printing Utilities*

---

### Description

`.print.via.format` is a “prototype” `print()` method, useful, at least as a start, by a simple

```
print.<myS3class> <- .print.via.format
```

### Usage

```
.print.via.format(x, ...)
```

### Arguments

`x` object to be printed.

`...` optional further arguments, passed to `format`.

**Value**

`x`, invisibly (by `invisible()`), as `print` methods should.

**See Also**

The `print` generic; its default method `print.default` (used for many basic implicit classes such as "numeric", "character" and `arrays` of them, `lists` etc).

**Examples**

```
## The function is simply defined as
function(x, ...) {
  writelines(format(x, ...))
  invisible(x)
}
```

## is used for simple print methods in R, and as prototype for new methods.

---

add\_datalist

---

Add a 'datalist' File to a Source Package

---

**Description**

The `data()` command with no arguments lists all the datasets available via data in attached packages, and to do so a per-package list is installed. Creating that list at install time can be slow for packages with huge datasets, and can be expedited by a supplying 'data/datalist' file.

**Usage**

```
add_datalist(pkgpath, force = FALSE, small.size = 1024^2)
```

**Arguments**

|                         |                                                                                                                                  |
|-------------------------|----------------------------------------------------------------------------------------------------------------------------------|
| <code>pkgpath</code>    | The path to a (source) package.                                                                                                  |
| <code>force</code>      | logical: can an existing 'data/datalist' file be over-written?                                                                   |
| <code>small.size</code> | number: a 'data/datalist' file is created only if the total size of the data files is larger than <code>small.size</code> bytes. |

**Details**

R CMD build will call this function to add a data list to packages with 1MB or more of file in the 'data' directory.

It can also be also helpful to give a 'data/datalist' file in packages whose datasets have many dependencies, including loading the packages itself (and maybe others).

**See Also**

`data`.

|                 |                                   |
|-----------------|-----------------------------------|
| assertCondition | <i>Asserting Error Conditions</i> |
|-----------------|-----------------------------------|

---

## Description

When testing code, it is not sufficient to check that results are correct, but also that errors or warnings are signalled in appropriate situations. The functions described here provide a convenient facility for doing so. The three functions check that evaluating the supplied expression produces an error, a warning or one of a specified list of conditions, respectively. If the assertion fails, an error is signalled.

## Usage

```
assertError(expr, classes = "error", verbose = FALSE)
assertWarning(expr, classes = "warning", verbose = FALSE)
assertCondition(expr, ..., .exprString = , verbose = FALSE)
```

## Arguments

|              |                                                                                                                                                                                                                                                                                                                                                       |
|--------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| expr         | an unevaluated R expression which will be evaluated via <code>tryCatch(expr, ..)</code> .                                                                                                                                                                                                                                                             |
| classes, ... | <a href="#">character</a> strings corresponding to the classes of the conditions that would satisfy the assertion; e.g., "error" or "warning". If none are specified, any condition will satisfy the assertion. See the details section.                                                                                                              |
| .exprString  | The string to be printed corresponding to expr. By default, the actual expr will be deparsed. Will be omitted if the function is supplied with the actual expression to be tested. If <code>assertCondition()</code> is called from another function, with the actual expression passed as an argument to that function, supply the deparsed version. |
| verbose      | If TRUE, a message is printed when the condition is satisfied.                                                                                                                                                                                                                                                                                        |

## Details

`assertCondition()` uses the general condition mechanism to check all the conditions generated in evaluating expr. The occurrence of any of the supplied condition classes among these satisfies the assertion regardless of what other conditions may be signalled.

`assertError()` is a convenience function for asserting errors; it calls `assertCondition()`.

`assertWarning()` asserts that a warning will be signalled, but *not* an error, whereas `assertCondition(expr, "warning")` will be satisfied even if an error follows the warning. See the examples.

## Value

If the assertion is satisfied, a list of all the condition objects signalled is returned, invisibly. See [conditionMessage](#) for the interpretation of these objects. Note that *all* conditions signalled during the evaluation are returned, whether or not they were among the requirements.

## Author(s)

John Chambers and Martin Maechler

**See Also**

[stop](#), [warning](#), [signalCondition](#), [tryCatch](#).

**Examples**

```

assertError(sqrt("abc"))
assertWarning(matrix(1:8, 4,3))

assertCondition( ""-1 ) # ok, any condition would satisfy this

try( assertCondition(sqrt(2), "warning") )
## .. Failed to get warning in evaluating sqrt(2)
  assertCondition(sqrt("abc"), "error") # ok
try( assertCondition(sqrt("abc"), "warning") )# -> error: had no warning
  assertCondition(sqrt("abc"), "error")
## identical to assertError() call above

assertCondition(matrix(1:5, 2,3), "warning")
try( assertCondition(matrix(1:8, 4,3), "error") )
## .. Failed to get expected error ...

## either warning or worse:
assertCondition(matrix(1:8, 4,3), "error","warning") # OK
assertCondition(matrix(1:8, 4, 3), "warning") # OK

## when both are signalled:
ff <- function() { warning("my warning"); stop("my error") }
  assertCondition(ff(), "warning")
## but assertWarning does not allow an error to follow
try(assertWarning(ff()))
  assertCondition(ff(), "error") # ok
assertCondition(ff(), "error", "warning") # ok (quietly, catching warning)

## assert that assertC..() does not assert [and use *one* argument only]
assertCondition( assertCondition(sqrt( 2 ), "warning") )
assertCondition( assertCondition(sqrt("abc"), "warning"), "error")
assertCondition( assertCondition(matrix(1:8, 4,3), "error"),
  "error")

```

---

basetools

*Base Package Tools*

---

**Description**

Tools for obtaining information about base packages.

**Usage**

```

base_aliases_db(verbose = FALSE, Ncpus = getOption("Ncpus", 1L))
base_rdxrefs_db(verbose = FALSE, Ncpus = getOption("Ncpus", 1L))

```

**Arguments**

|         |                                                           |
|---------|-----------------------------------------------------------|
| verbose | logical. Should packages be listed as they are processed? |
| Ncpus   | the number of parallel processes to use for processing.   |

## Details

`base_aliases_db()` returns the Rd aliases in the base packages, as a nested per-package named list of per-Rd-file named lists with the aliases.

`base_rdxrefs_db()` returns the Rd cross-references in the base packages, as a per-package list of matrices with columns "Target", "Anchor" and "Source".

## See Also

---

 bibstyle

*Select or Define a Bibliography Style*

---

## Description

This function defines and registers styles for rendering [bibentry](#) objects into 'Rd' format, for later conversion to text, HTML, etc.

## Usage

```
bibstyle(style, envir, ..., .init = FALSE, .default = TRUE)
getBibstyle(all = FALSE)
```

## Arguments

|                       |                                                                         |
|-----------------------|-------------------------------------------------------------------------|
| <code>style</code>    | A character string naming the style.                                    |
| <code>envir</code>    | (optional) An environment holding the functions to implement the style. |
| <code>...</code>      | Named arguments to add to the environment.                              |
| <code>.init</code>    | Whether to initialize the environment from the default style "JSS".     |
| <code>.default</code> | Whether to set the specified style as the default style.                |
| <code>all</code>      | Whether to return the names of all registered styles.                   |

## Details

Rendering of [bibentry](#) objects may be done using routines modelled after those used by BibTeX. This function allows environments to be created and manipulated to contain those routines.

There are two ways to create a new style environment. The easiest is to set `.init = TRUE`, in which case the environment will be initialized with a copy of the default "JSS" environment. (This style is modelled after the 'jss.bst' style used by the *Journal of Statistical Software*.) Alternatively, the `envir` argument can be used to specify a completely new style environment.

To find the name of the default style, use `getBibstyle()`. To retrieve an existing style without setting it as the default, use `bibstyle(style, .default = FALSE)`. To modify an existing style, specify style and some named entries via `...` (Modifying the default "JSS" style is discouraged.) Setting style to NULL or leaving it missing will retrieve the default style, but modifications will not be allowed.

At a minimum, the environment should contain routines to render each of the 12 types of bibliographic entry supported by [bibentry](#) as well as several other routines described below. The former must be named `formatArticle`, `formatBook`, `formatInbook`,

`formatIncollection`, `formatInProceedings`, `formatManual`, `formatMastersthesis`, `formatMisc`, `formatPhdthesis`, `formatProceedings`, `formatTechreport` and `formatUnpublished`. Each of these takes one argument, a single `unclass`'ed entry from the `bibentry` vector passed to the renderer, and should produce a single element character vector (possibly containing newlines).

The other routines are as follows. `sortKeys`, a function to produce a sort key to sort the entries, is passed the original `bibentry` vector and should produce a sortable vector of the same length to define the sort order. Finally, the optional function `cite` should have the same argument list as `utils::cite`, and should produce a citation to be used in text.

The `format` method for "bibentry" objects adds a field named `".index"` to each entry after sorting and before formatting. This is a 1-based index within the complete object that can be used in styles that require numbering. Although the "JSS" style doesn't use numbers, it includes a `fmtPrefix()` stub function that may be used to display them. See the example below.

## Value

`bibstyle` returns the environment which has been selected or created.

`getBibstyle` returns the name of the default style, or all style names.

|---------------|---------------------------|
| buildVignette | <i>Build One Vignette</i> |
|---------------|---------------------------|

---

**Description**

Run [Sweave](#) (or other custom weave function), [texi2pdf](#), and/or [Stangle](#) (or other custom tangle function) on one vignette.

This is the workhorse of R CMD Sweave.

**Usage**

```
buildVignette(file, dir = ".", weave = TRUE, latex = TRUE, tangle = TRUE,
              quiet = TRUE, clean = TRUE, keep = character(),
              engine = NULL, buildPkg = NULL, encoding, ...)
```

**Arguments**

|          |                                                                                                                                                                                                                                                                                  |
|----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| file     | character; the vignette source file.                                                                                                                                                                                                                                             |
| dir      | character; the working directory in which the intermediate and output files will be produced.                                                                                                                                                                                    |
| weave    | logical; should weave be run?                                                                                                                                                                                                                                                    |
| latex    | logical; should <a href="#">texi2pdf</a> be run if weaving produces a ‘.tex’ file?                                                                                                                                                                                               |
| tangle   | logical; should tangle be run?                                                                                                                                                                                                                                                   |
| quiet    | logical; run in quiet mode?                                                                                                                                                                                                                                                      |
| clean    | logical; whether to remove some newly created, often intermediate, files. See details below.                                                                                                                                                                                     |
| keep     | a list of file names to keep in any case when cleaning. Note that “target” files are kept anyway.                                                                                                                                                                                |
| engine   | NULL or character; name of vignette engine to use. Overrides any ‘\VignetteEngine{ }’ markup in the vignette.                                                                                                                                                                    |
| buildPkg | NULL or a character vector; optional packages in which to find the vignette engine.                                                                                                                                                                                              |
| encoding | the encoding to assume for the file. If not specified, it will be read if possible from the file’s contents. Note that if the vignette is part of a package, <a href="#">buildVignettes</a> reads the package’s encoding from the ‘DESCRIPTION’ file but this function does not. |
| ...      | Additional arguments passed to weave and tangle.                                                                                                                                                                                                                                 |

**Details**

This function determines the vignette engine for the vignette (default `utils::Sweave`), then weaves and/or tangles the vignette using that engine. Finally, if `clean` is `TRUE`, newly created intermediate files (non “targets”, where these depend on the engine, etc, and not any in `keep`) will be deleted. If `clean` is `NA`, and `weave` is true, newly created intermediate output files (e.g., ‘.tex’) will not be deleted even if a ‘.pdf’ file has been produced from them.

If `buildPkg` is specified, those packages will be loaded before the vignette is processed and will be used as the default packages in the search for a vignette engine, but an explicitly specified package

in the vignette source (e.g., using ‘\VignetteEngine{utils::Sweave}’ to specify the Sweave engine in the **utils** package) will override it. In contrast, if the engine argument is given, it will override the vignette source.

### Value

A character vector naming the files that have been produced.

### Author(s)

Henrik Bengtsson and Duncan Murdoch

### See Also

[buildVignettes](#) for building all vignettes in a package.

|----------------|-----------------------------------------|
| buildVignettes | <i>List and Build Package Vignettes</i> |
|----------------|-----------------------------------------|

---

### Description

Run [Sweave](#) (or other custom weave function) and [texi2pdf](#) on all vignettes of a package, or list the vignettes.

### Usage

```
buildVignettes(package, dir, lib.loc = NULL, quiet = TRUE,
               clean = TRUE, tangle = FALSE, skip = NULL,
               ser_elibs = NULL)
```

```
pkgVignettes(package, dir, subdirs = NULL, lib.loc = NULL,
              output = FALSE, source = FALSE, check = FALSE)
```

### Arguments

|           |                                                                                                                                                                                                                                                         |
|-----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| package   | a character string naming an installed package. If given, vignette source files are by default looked for in subdirectory ‘doc’.                                                                                                                        |
| dir       | a character string specifying the path to a package’s root source directory. If given, vignette source files are by default looked for in subdirectory ‘vignettes’.                                                                                     |
| lib.loc   | a character vector of directory names of R libraries, or NULL. The default value of NULL corresponds to all libraries currently known. The specified library trees are used to search for package.                                                      |
| quiet     | logical. Weave and run <a href="#">texi2pdf</a> in quiet mode.                                                                                                                                                                                          |
| clean     | Remove all files generated by the build, even if there were copies there before.                                                                                                                                                                        |
| tangle    | logical. Do tangling as well as weaving.                                                                                                                                                                                                                |
| skip      | a character vector of names of vignettes (without file extension, matching the names returned from <code>pkgVignettes</code> ) which should be skipped, or TRUE to skip those with unavailable ‘\VignetteDepends’ (from <a href="#">vignetteInfo</a> ). |
| ser_elibs | For use from R CMD check.                                                                                                                                                                                                                               |

|         |                                                                                                                                                                                                                                                          |
|---------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| subdirs | a character vector of subdirectories of <code>dir</code> in which to look for vignettes. The first which exists is used. Defaults to "doc" if package is supplied, otherwise "vignettes".                                                                |
| output  | logical indicating if the output filenames for each vignette should be returned (in component outputs).                                                                                                                                                  |
| source  | logical indicating if the <i>tangled</i> output filenames for each vignette should be returned (in component sources).                                                                                                                                   |
| check   | logical. If TRUE, check whether all files that have vignette-like filenames have an identifiable vignette engine. This may be a false positive if a file is not a vignette but has a filename matching a pattern defined by one of the vignette engines. |

Details

`buildVignettes` is used by R CMD build and R CMD check to (re-)build vignette outputs from their sources.

As from R 3.4.1, both of these functions ignore files that are listed in the `‘.Rbuildignore’` file in `dir`.

Value

`buildVignettes` is called for its side effect of creating the outputs of all vignettes, and if `tangle = TRUE`, extracting the R code.

`pkgVignettes` returns an object of class "pkgVignettes" if a vignette directory is found, otherwise NULL.

Examples

```
gVigns <- pkgVignettes("grid")
str(gVigns)
```

| charsets | <i>Conversion Tables between Character Sets</i> |
|----------|-------------------------------------------------|

---

Description

`charset_to_Unicode` is a matrix of Unicode code points with columns for the common 8-bit encodings.

`Adobe_glyphs` is a data frame which gives Adobe glyph names for Unicode code points. It has two character columns, "adobe" and "unicode" (a 4-digit hex representation).

Usage

```
charset_to_Unicode

Adobe_glyphs
```

## Details

charset\_to\_Unicode is an integer matrix of class `c("noquote", "hexmode")` so prints in hexadecimal. The mappings are those used by libiconv: there are differences in the way quotes and minus/hyphen are mapped between sources (and the postscript encoding files use a different mapping).

Adobe\_glyphs includes all the Adobe glyph names which correspond to single Unicode characters. It is sorted by Unicode code point and within a point alphabetically on the glyph (there can be more than one name for a Unicode code point). The data are in the file '[R\\_HOME/share/encodings/Adobe\\_glyphlist](#)'.

## Examples

```
## find Adobe names for ISOLatin2 chars.
latin2 <- charset_to_Unicode[, "ISOLatin2"]
aUnicode <- as.hexmode(paste0("0x", Adobe_glyphs$unicode))
keep <- aUnicode %in% latin2
aUnicode <- aUnicode[keep]
aAdobe <- Adobe_glyphs[keep, 1]
## first match
aLatin2 <- aAdobe[match(latin2, aUnicode)]
## all matches
bLatin2 <- lapply(1:256, function(x) aAdobe[aUnicode == latin2[x]])
format(bLatin2, justify = "none")
```

---

checkFF

*Check Foreign Function Calls*

---

## Description

Performs checks on calls to compiled code from R code. Currently only checks whether the interface functions such as `.C` and `.Fortran` are called with a "[NativeSymbolInfo](#)" first argument or with argument `PACKAGE` specified, which is highly recommended to avoid name clashes in foreign function calls.

## Usage

```
checkFF(package, dir, file, lib.loc = NULL,
        registration = FALSE, check_DUP = FALSE,
        verbose = getOption("verbose"))
```

## Arguments

- |         |                                                                                                                                                                        |
|---------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| package | a character string naming an installed package. If given, the installed R code of the package is checked.                                                              |
| dir     | a character string specifying the path to a package's root source directory. This should contain the subdirectory 'R' (for R code). Only used if package is not given. |
| file    | the name of a file containing R code to be checked. Used if neither package nor dir are given.                                                                         |

|                           |                                                                                                                                                                                                    |
|---------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>lib.loc</code>      | a character vector of directory names of R libraries, or NULL. The default value of NULL corresponds to all libraries currently known. The specified library trees are used to search for package. |
| <code>registration</code> | a logical. If TRUE, checks the registration information on the call (if available).                                                                                                                |
| <code>check_DUP</code>    | a logical. If TRUE, .C and .Fortran calls with DUP = FALSE are reported.                                                                                                                           |
| <code>verbose</code>      | a logical. If TRUE, additional diagnostics are printed (and the result is returned invisibly).                                                                                                     |

### Details

Note that we can only check if the name argument is a symbol or a character string, not what class of object the symbol resolves to at run-time.

If the package has a namespace which contains a `useDynLib` directive, calls in top-level functions in the package are not reported as their symbols will be preferentially looked up in the DLL named in the first `useDynLib` directive.

This checks that calls with PACKAGE specified are to the same package, and reports separately those which are in base packages and those which are in other packages (and if those packages are specified in the 'DESCRIPTION' file).

### Value

An object of class "checkFF".

There are `format` and `print` methods to display the information contained in such objects.

### See Also

`.C`, `.Fortran`; `Foreign`.

### Examples

```
# order is pretty much random
checkFF(package = "stats", verbose = TRUE)
```

---

checkMD5sums

*Check and Create MD5 Checksum Files*

---

### Description

checkMD5sums checks the files against a file 'MD5'.

### Usage

```
checkMD5sums(package, dir)
```

### Arguments

|                      |                                                              |
|----------------------|--------------------------------------------------------------|
| <code>package</code> | the name of an installed package                             |
| <code>dir</code>     | the path to the top-level directory of an installed package. |

## Details

The file ‘MD5’ which is created is in a format which can be checked by `md5sum -c MD5` if a suitable command-line version of `md5sum` is available. (For Windows, one is supplied in the bundle at <https://cran.r-project.org/bin/windows/Rtools/>.)

If `dir` is missing, an installed package of name `package` is searched for.

The private function `tools:::installMD5sums` is used to create MD5 files in the Windows build.

## Value

`checkMD5sums` returns a logical, NA if there is no ‘MD5’ file to be checked.

## See Also

[md5sum](#)

---

checkPoFiles

*Check Translation Files for Inconsistent Format Strings*

---

## Description

These functions compare formats embedded in English messages with translated strings to check for consistency. `checkPoFile` checks one file, while `checkPoFiles` checks all files for specified or all languages.

## Usage

```
checkPoFile(f, strictPlural = FALSE)
checkPoFiles(language, dir = ".")
```

## Arguments

|                           |                                                                                                                                                                                                                     |
|---------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>f</code>            | a character string giving a single filepath.                                                                                                                                                                        |
| <code>strictPlural</code> | whether to compare formats of singular and plural forms in a strict way.                                                                                                                                            |
| <code>language</code>     | a character string giving a language code, or a ‘ <a href="#">regexp</a> ’ (regular expression), to match languages in <code>dir</code> . Use <code>""</code> to denote all languages in the <code>dir</code> path. |
| <code>dir</code>          | a path to a directory in which to check files.                                                                                                                                                                      |

## Details

Part of R’s internationalization depends on translations of messages in ‘.po’ files. In these files an ‘English’ message taken from the R sources is followed by a translation into another language. Many of these messages are format strings for C or R [sprintf](#) and related functions. In these cases, the translation must give a compatible format or an error will be generated when the message is displayed.

The rules for compatibility differ between C and R in several ways. C supports several conversions not supported by R, namely `c`, `u`, `p`, `n`. It is allowed in C’s `sprintf()` function to have more arguments than are needed by the format string, but in R the counts must match exactly. R requires types of arguments to match, whereas C will do the display whether it makes sense or not.

These functions compromise on the testing as follows. The additional formats allowed in C are accepted, and all differences in argument type or count are reported. As a consequence some reported differences are not errors.

If the `strictPlural` argument is `TRUE`, then argument lists must agree exactly between singular and plural forms of messages; if `FALSE`, then translations only need to match one or the other of the two forms. When `checkPoFiles` calls `checkPoFile`, the `strictPlural` argument is set to `TRUE` for files with names starting 'R-', and to `FALSE` otherwise.

Items marked as 'fuzzy' in the '.po' file are not processed (as they are ignored by the message compiler).

If a difference is found, the translated string is checked for variant percent signs (e.g., the wide percent sign "\uFF05"). Such signs will not be recognized as format specifiers, and are likely to be errors.

### Value

Both functions return an object of S3 class "check\_po\_files". A print method is defined for this class to display a report on the differences.

### Author(s)

Duncan Murdoch

### References

See the GNU gettext manual for the '.po' file format:  
<https://www.gnu.org/software/gettext/manual/gettext.html>.

### See Also

`update_pkg_po()` which calls `checkPoFile()`; `xgettext`, `sprintf`.

### Examples

```
## Not run:
checkPoFiles("de", "/path/to/R/src/directory")

## End(Not run)
```

---

checkRd

*Check an Rd Object*

---

### Description

Check an help file or the output of the `parse_Rd` function.

### Usage

```
checkRd(Rd, defines = .Platform$OS.type, stages = "render",
        unknownOK = TRUE, listOK = TRUE, ..., def_enc = FALSE)
```

## Arguments

|           |                                                                                                                                          |
|-----------|------------------------------------------------------------------------------------------------------------------------------------------|
| Rd        | a filename or Rd object to use as input.                                                                                                 |
| defines   | string(s) to use in <code>#ifdef</code> tests.                                                                                           |
| stages    | at which stage ("build", "install", or "render") should <code>\Sexpr</code> macros be executed? See the notes below.                     |
| unknownOK | unrecognized macros are treated as errors if FALSE, otherwise warnings.                                                                  |
| listOK    | unnecessary non-empty braces (e.g., around text, not as an argument) are treated as errors if FALSE, otherwise warnings ("Lost braces"). |
| ...       | additional parameters to pass to <code>parse_Rd</code> when Rd is a filename. One that is often useful is encoding.                      |
| def_enc   | logical: has the package declared an encoding, so tests for non-ASCII text are suppressed?                                               |

## Details

checkRd performs consistency checks on an Rd file, confirming that required sections are present, etc.

It accepts a filename for an Rd file, and will use `parse_Rd` to parse it before applying the checks. If so, warnings from `parse_Rd` are collected, together with those from the internal function `prepare_Rd`, which does the `#ifdef` and `\Sexpr` processing, drops sections that would not be rendered or are duplicated (and should not be) and removes empty sections.

An Rd object is passed through `prepare_Rd`, but it may already have been (and installed Rd objects have).

Warnings are given a 'level': those from `prepare_Rd` have level 0. These include

```
\Sexpr expects R code; found ...
Unprocessed 'stage' macro from stage-stage \Sexpr
All text must be in a section
Only one tag name section is allowed: the first will be used
docType type is unrecognized
Section name is unrecognized and will be dropped
Dropping empty section name
```

checkRd itself can show

```
7 Tag tag name not recognized
7 Unrecognized format: ...
7 \tabular format must be simple text
7 Unrecognized \tabular format: ...
7 Only n columns allowed in this table
7 Tag tag name is invalid in a block name block
7 \method not valid outside a code block
7 Tag \method is only valid in \usage
7 Tag \dontrun is only valid in \examples
7 Invalid email address: ...
7 Invalid URL: ...
5 \name should not contain !, | or @
5 \item in block name must have non-empty label
```

- 3 Empty section *tag name*
- 1 \name should only contain printable ASCII characters
- 1 Non-ASCII contents without declared encoding
- 1 Non-ASCII contents in second part of \enc
- 1 Escaped LaTeX specials: ...
- 1-3 Lost braces ...
- 3 Tag \ldots is invalid in a code block
- 5 \title should not end in a period

and variations with \method replaced by \S3method or \S4method, \dontrun replaced by \donttest, \dontdiff or \dontshow, and \title replaced by \section or \subsection name. “Lost braces” are uprated to warning level -1 when they match common markup mistakes, e.g., ‘code{text}’ rendered as ‘codetext’ due to the missing backslash escape for the macro name.

Note that both prepare\_Rd and checkRd have tests for an empty section: that in checkRd is stricter (essentially that nothing is output).

## Value

This may fail through an R error, but otherwise warnings are collected as returned as an object of class “checkRd”, a character vector of messages. This class has a print method which only prints unique messages, and has argument minlevel that can be used to select only more serious messages. (This is set to -1 in R CMD check.)

Possible fatal errors are those from !unknownOK or !listOK, from invalid \if or \ifelse conditions, from running the parser (e.g., a non-existent file, unclosed quoted string, non-ASCII input without a specified encoding, an invalid value for an \Sexpr option), or from prepare\_Rd (multiple \Rdversion declarations, invalid \encoding or \docType or \name sections, and missing or duplicate \name or \title sections), including errors from parsing/running code from \Sexpr macros (if covered by stages).

## See Also

[parse\\_Rd](#), [Rd2HTML](#).

## Examples

```
## parsed Rd from the installed version of _this_ help file
rd <- Rd_db("tools")["checkRd.Rd"]
rd
stopifnot(length(checkRd(rd)) == 0) # there should be no issues

## make up \tabular issues
bad <- r"(\name{bad}\title{bad}\description{\tabular{p}{1 \tab 2}})"
(res <- checkRd(parse_Rd(textConnection(bad))))
stopifnot(length(res) > 0)
```

**Description**

This reports for each of the files produced by `save` the size, if it was saved in ASCII or XDR binary format, and if it was compressed (and if so in what format).

Usually such files have extension `‘.rda’` or `‘.RData’`, hence the name of the function.

**Usage**

```
checkRdaFiles(paths)
resaveRdaFiles(paths, compress = c("auto", "gzip", "bzip2", "xz"),
               compression_level, version = NULL)
```

**Arguments**

|                                          |                                                                                                                                                                                     |
|------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>paths</code>                       | A character vector of paths to save files. If this specifies a single directory, it is taken to refer to all <code>‘.rda’</code> and <code>‘.RData’</code> files in that directory. |
| <code>compress, compression_level</code> | Type and level of compression: see <a href="#">save</a> . Values of <code>compress</code> can be abbreviated.                                                                       |
| <code>version</code>                     | The format to be used when re-saving: see <a href="#">save</a> .                                                                                                                    |

**Details**

`compress = "auto"` asks `R` to choose the compression and ignores `compression_level`. It will try `"gzip"`, `"bzip2"` and if the `"gzip"` compressed size is over 10Kb, `"xz"` and choose the smallest compressed file (but with a 10% bias towards `"gzip"`). This can be slow.

For back-compatibility, `version = NULL` is interpreted to mean version 2: however version-3 files will only be saved as version 3.

**Value**

For `checkRdaFiles`, a data frame with rows names `paths` and columns

|                       |                                                                                                                                                                                                                                                                |
|-----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>size</code>     | numeric: file size in bytes, NA if the file does not exist.                                                                                                                                                                                                    |
| <code>ASCII</code>    | logical: true for <code>save(ASCII = TRUE)</code> , NA if the format is not that of an <code>R</code> save file.                                                                                                                                               |
| <code>compress</code> | character: type of compression. One of <code>"gzip"</code> , <code>"bzip2"</code> , <code>"xz"</code> , <code>"none"</code> or <code>"unknown"</code> (which means that if this is an <code>R</code> save file it is from a later version of <code>R</code> ). |
| <code>version</code>  | integer: positive with the version(s) of the <a href="#">save()</a> , see there on which versions have been default in which versions of <code>R</code> , and NA for non-Rda files.                                                                            |

## Examples

```
## Not run:
## from a package top-level source directory
paths <- sort(Sys.glob(c("data/*.rda", "data/*.RData")))
(res <- checkRdaFiles(paths))
## pick out some that may need attention
bad <- is.na(res$ASCII) | res$ASCII | (res$size > 1e4 & res$compress == "none")
res[bad, ]

## End(Not run)
```

checkTnF

*Check R Packages or Code for T/F*

## Description

Checks the specified R package or code file for occurrences of T or F, and gathers the expression containing these. This is useful as in R T and F are just variables which are set to the logicals TRUE and FALSE by default, but are not reserved words and hence can be overwritten by the user. Hence, one should always use TRUE and FALSE for the logicals.

## Usage

```
checkTnF(package, dir, file, lib.loc = NULL)
```

## Arguments

|         |                                                                                                                                                                                                                                                                                                            |
|---------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| package | a character string naming an installed package. If given, the installed R code and the examples in the documentation files of the package are checked. R code installed as an image file cannot be checked.                                                                                                |
| dir     | a character string specifying the path to a package's root source directory. This must contain the subdirectory 'R' (for R code), and should also contain 'man' (for documentation). Only used if package is not given. If used, the R code files and the examples in the documentation files are checked. |
| file    | the name of a file containing R code to be checked. Used if neither package nor dir are given.                                                                                                                                                                                                             |
| lib.loc | a character vector of directory names of R libraries, or NULL. The default value of NULL corresponds to all libraries currently known. The specified library trees are used to search for package.                                                                                                         |

## Value

An object of class "checkTnF" which is a list containing, for each file where occurrences of T or F were found, a list with the expressions containing these occurrences. The names of the list are the corresponding file names.

There is a print method for nicely displaying the information contained in such objects.

checkVignettes

*Check Package Vignettes***Description**

Check all vignettes of a package by running [Sweave](#) (or other custom weave function) and/or [Stangle](#) (or other custom tangle function) on them. All R source code files found after the tangle step are [sourced](#) to check whether all code can be executed without errors.

**Usage**

```
checkVignettes(package, dir, lib.loc = NULL,
               tangle = TRUE, weave = TRUE, latex = FALSE,
               workdir = c("tmp", "src", "cur"),
               keepfiles = FALSE)
```

**Arguments**

|           |                                                                                                                                                                                                                                                                       |
|-----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| package   | a character string naming an installed package. If given, vignette source files are looked for in subdirectory ‘doc’.                                                                                                                                                 |
| dir       | a character string specifying the path to a package’s root source directory. If given, vignette source files are looked for in subdirectory ‘vignettes’.                                                                                                              |
| lib.loc   | a character vector of directory names of R libraries, or NULL. The default value of NULL corresponds to all libraries currently known. The specified library trees are used to search for package.                                                                    |
| tangle    | Perform a tangle and <a href="#">source</a> the extracted code?                                                                                                                                                                                                       |
| weave     | Perform a weave?                                                                                                                                                                                                                                                      |
| latex     | logical: if weave and latex are TRUE and there is no ‘Makefile’ in the vignettes directory, run the intermediate ‘.tex’ outputs from weaving through <a href="#">texi2pdf</a> .                                                                                       |
| workdir   | Directory used as working directory while checking the vignettes. If “tmp” then a temporary directory is created, this is the default. If “src” then the directory containing the vignettes itself is used, if “cur” then the current working directory of R is used. |
| keepfiles | Delete files in the temporary directory? This option is ignored when workdir != “tmp”.                                                                                                                                                                                |

**Details**

This function first uses [pkgVignettes](#) to find the package vignettes, and in particular their vignette engines (see [vignetteEngine](#)).

If tangle is true, it then runs [Stangle](#) (or other custom tangle function provided by the engine) to produce (one or more) R code files from each vignette, then [sources](#) each code file in turn.

If weave is true, the vignettes are run through [Sweave](#) (or other custom weave function provided by the engine). If latex is also true and there is no ‘Makefile’ in the vignettes directory, [texi2pdf](#) is run on the intermediate ‘.tex’ files from weaving for those vignettes which did not give errors in the previous steps.

**Value**

An object of class "checkVignettes", which is a list with the error messages found during the tangle, source, weave and latex steps. There is a print method for displaying the information contained in such objects.

---

check\_packages\_in\_dir *Check Source Packages and Their Reverse Dependencies*

---

**Description**

Check source packages in a given directory, optionally with their reverse dependencies.

**Usage**

```
check_packages_in_dir(dir,
                      pfiles = Sys.glob("*.tar.gz"),
                      check_args = character(),
                      check_args_db = list(),
                      reverse = NULL,
                      check_env = character(),
                      xvfb = FALSE,
                      Ncpus = getOption("Ncpus", 1L),

**Arguments**

|            |                                                                                                                                                                                           |
|------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| dir        | a character string giving the path to the directory with the source ‘.tar.gz’ files to be checked.                                                                                        |
| pfiles     | (optional) character vector of tarball files to be checked. Useful for choosing a subset of the ‘.tar.gz’ files in dir.                                                                   |
| check_args | a character vector with arguments to be passed to R CMD check, or a list of length two of such character vectors to be used for checking packages and reverse dependencies, respectively. |

|               |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| check_args_db | a named list of character vectors with arguments to be passed to R CMD check, with names the respective package names.                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| reverse       | a list with names partially matching "repos", "which", or "recursive", giving the repositories to use for locating reverse dependencies (a subset of <code>getOption("repos")</code> , the default), the types of reverse dependencies (default: <code>c("Depends", "Imports", "LinkingTo")</code> , with shorthands "most" and "all" as for <a href="#">package_dependencies</a> ), and indicating whether to also check reverse dependencies of reverse dependencies and so on (default: FALSE), or NULL (default), in which case no reverse dependencies are checked. |
| check_env     | a character vector of name=value strings to set environment variables for checking, or a list of length two of such character vectors to be used for checking packages and reverse dependencies, respectively.                                                                                                                                                                                                                                                                                                                                                           |
| xvfb          | a logical indicating whether to perform checking inside a virtual framebuffer X server (Unix only), or a character vector of Xvfb options for doing so.                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Ncpus         | the number of parallel processes to use for parallel installation and checking.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| clean         | a logical indicating whether to remove the downloaded reverse dependency sources.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| install_args  | list of arguments to be passed to underlying <a href="#">install.packages</a> call.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| parallel_args | list of arguments to be passed to underlying calls of <a href="#">parLapply</a> (on Windows) or <a href="#">mclapply</a> (on other OS).                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| ...           | passed to <a href="#">readLines</a> , e.g. for reading log files produced in a different encoding; currently not used by <code>check_packages_in_dir</code> .                                                                                                                                                                                                                                                                                                                                                                                                            |
| all           | a logical indicating whether to also summarize the reverse dependencies checked.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| full          | a logical indicating whether to also give details for checks with non-ok results, or summarize check example timings (if available).                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| which         | see <a href="#">package_dependencies</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| old           | a character string giving the path to the directory of a previous <code>check_packages_in_dir</code> run.                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| outputs       | a logical indicating whether to analyze changes in the outputs of the checks performed, or only (default) the status of the checks.                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| sources       | a logical indicating whether to also investigate the changes in the source files checked (default: FALSE).                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| logs          | a character vector with the paths of '00check.log' to analyze. Only used if <code>dir</code> was not given.                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| drop_ok       | a logical indicating whether to drop checks with 'ok' status, or a character vector with the 'ok' status tags to drop. The default corresponds to tags 'OK', 'NONE' and 'SKIPPED'.                                                                                                                                                                                                                                                                                                                                                                                       |

## Details

`check_packages_in_dir` allows to conveniently check source package '.tar.gz' files in the given directory `dir`, along with their reverse dependencies as controlled by `reverse`.

The "which" component of `reverse` can also be a list, in which case reverse dependencies are obtained for each element of the list and the corresponding element of the "recursive" component of `reverse` (which is recycled as needed).

If needed, the source '.tar.gz' files of the reverse dependencies to be checked as well are downloaded into `dir` (and removed at the end if `clean` is true). Next, all packages (additionally) needed

for checking are installed to the 'Library' subdirectory of dir. Then, all '.tar.gz' files are checked using the given arguments and environment variables, with outputs and messages to files in the 'Outputs' subdirectory of dir. The '\*.Rcheck' directories with the check results of the reverse dependencies are renamed by prefixing their base names with 'rdepends\_'.

Results and timings can conveniently be summarized using `summarize_check_packages_in_dir_results` and `summarize_check_packages_in_dir_timings`, respectively.

Installation and checking is performed in parallel if `Ncpus` is greater than one: this will use `mclapply` on Unix and `parLapply` on Windows.

`check_packages_in_dir` returns an object inheriting from class "check\_packages\_in\_dir" which has `print` and `summary` methods.

`check_packages_in_dir_changes` allows to analyze the effect of changing (some of) the sources. With `dir` and `old` the paths to the directories with the new and old sources, respectively, and the corresponding check results, possible changes in the check results can conveniently be analyzed as controlled via options `outputs` and `sources`. The changes object returned can be subscripted according to change in severity from the old to the new results by using one of "=", "!", "<", "<=", ">" or ">=" as row index.

`check_packages_in_dir_details` analyzes check log files to obtain check details as a data frame which can be used for further processing, providing check name, status and output for every check performed and not dropped according to status tag (via variables `Check`, `Status` and `Output`, respectively).

Environment variable `_R_CHECK_ELAPSED_TIMEOUT_` can be used to set a limit on the elapsed time of each check run. See the 'R Internals' manual for how the value is interpreted and for other environment variables which can be used for finer-grained control on timeouts within a check run.

## Note

This functionality is still experimental: interfaces may change in future versions.

## Examples

```
## Not run:
## Check packages in dir without reverse dependencies:
check_packages_in_dir(dir)
## Check packages in dir and their reverse dependencies using the
## defaults (all repositories in getOption("repos"), all "strong"
## reverse dependencies, no recursive reverse dependencies):
check_packages_in_dir(dir, reverse = list())
## Check packages in dir with their reverse dependencies from CRAN,
## using all strong reverse dependencies and reverse suggests:
check_packages_in_dir(dir,
                      reverse = list(repos = getOption("repos")["CRAN"],
                                     which = "most"))
## Check packages in dir with their reverse dependencies from CRAN,
## using '--as-cran' for the former but not the latter:
check_packages_in_dir(dir,
                      check_args = c("--as-cran", ""),
                      reverse = list(repos = getOption("repos")["CRAN"]))

## End(Not run)
```

codoc

*Check Code/Documentation Consistency***Description**

Find inconsistencies between actual and documented ‘structure’ of R objects in a package. `codoc` compares names and optionally also corresponding positions and default values of the arguments of functions. `codocClasses` and `codocData` compare slot names of S4 classes and variable names of data sets, respectively.

**Usage**

```
codoc(package, dir, lib.loc = NULL,
      use.values = NULL, verbose = getOption("verbose"))
codocClasses(package, lib.loc = NULL)
codocData(package, lib.loc = NULL)
```

**Arguments**

|                         |                                                                                                                                                                                                                                          |
|-------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>package</code>    | a character string naming an installed package.                                                                                                                                                                                          |
| <code>dir</code>        | a character string specifying the path to a package’s root source directory. This must contain the subdirectories ‘man’ with R documentation sources (in Rd format) and ‘R’ with R code. Only used if <code>package</code> is not given. |
| <code>lib.loc</code>    | a character vector of directory names of R libraries, or <code>NULL</code> . The default value of <code>NULL</code> corresponds to all libraries currently known. The specified library trees are used to search for package.            |
| <code>use.values</code> | if <code>FALSE</code> , do not use function default values when comparing code and docs. Otherwise, compare <i>all</i> default values if <code>TRUE</code> , and only the ones documented in the usage otherwise (default).              |
| <code>verbose</code>    | a logical. If <code>TRUE</code> , additional diagnostics are printed.                                                                                                                                                                    |

**Details**

The purpose of `codoc` is to check whether the documented usage of function objects agrees with their formal arguments as defined in the R code. This is not always straightforward, in particular as the usage information for methods to generic functions often employs the name of the generic rather than the method.

The following algorithm is used. If an installed package is used, it is loaded (unless it is the **base** package), after possibly detaching an already loaded version of the package. Otherwise, if the sources are used, the R code files of the package are collected and sourced in a new environment. Then, the usage sections of the Rd files are extracted and parsed ‘as much as possible’ to give the formals documented. For interpreted functions in the code environment, the formals are compared between code and documentation according to the values of the argument `use.values`.

If a package has a namespace both exported and unexported objects are checked, as well as registered S3 methods. (In the unlikely event of differences the order is exported objects in the package, registered S3 methods and finally objects in the namespace and only the first found is checked.)

Currently, the R documentation format has no high-level markup for the basic ‘structure’ of classes and data sets (similar to the usage sections for function synopses). Variable names for data frames in documentation objects obtained by suitably editing ‘templates’ created by `prompt` are recognized

by `codocData` and used provided that the documentation object is for a single data frame (i.e., only has one alias). `codocClasses` analogously handles slot names for classes in documentation objects obtained by editing shells created by [promptClass](#).

Help files named '*pkgname*-defunct.Rd' for the appropriate *pkgname* are checked more loosely, as they may have undocumented arguments.

### Value

`codoc` returns an object of class "`codoc`". Currently, this is a list which, for each Rd object in the package where an inconsistency was found, contains an element with a list of the mismatches (which in turn are lists with elements `code` and `docs`, giving the corresponding arguments obtained from the function's code and documented usage).

`codocClasses` and `codocData` return objects of class "`codocClasses`" and "`codocData`", respectively, with a structure similar to class "`codoc`".

There are print methods for nicely displaying the information contained in such objects.

### Note

The default for `use.values` has been changed from `FALSE` to `NULL`, for R versions 1.9.0 and later.

compactPDF

*Compact PDF Files*

---

### Description

Re-save PDF files (especially vignettes) more compactly. Support function for R CMD build `--compact-vignettes`.

### Usage

```
compactPDF(paths,
            qpdf = Sys.which(Sys.getenv("R_QPDF", "qpdf")),
            gs_cmd = Sys.getenv("R_GSCMD", ""),
            gs_quality = Sys.getenv("GS_QUALITY", "none"),
            gs_extras = character(),
            verbose = FALSE)
```

```
## S3 method for class 'compactPDF'
format(x, ratio = 0.9, diff = 1e4, ...)
```

### Arguments

|                    |                                                                                                                                                                     |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>paths</code> | A character vector of paths to PDF files, or a length-one character vector naming a directory, when all ' <code>.pdf</code> ' files in that directory will be used. |
| <code>qpdf</code>  | Character string giving the path to the <code>qpdf</code> command. If empty, <code>qpdf</code> will not be used.                                                    |

|                          |                                                                                                                                                                                                                                                                    |
|--------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>gs_cmd</code>      | Character string giving the path to the GhostScript executable, if that is to be used. On Windows this is the path to 'gswin32c.exe' or 'gswin64c.exe'. If "" (the default), the function will try to find a platform-specific path to GhostScript where required. |
| <code>gs_quality</code>  | A character string indicating the quality required: the options are "none" (so GhostScript is not used), "printer" (300dpi), "ebook" (150dpi) and "screen" (72dpi). Can be abbreviated.                                                                            |
| <code>gs_extras</code>   | An optional character vector of further options to be passed to GhostScript.                                                                                                                                                                                       |
| <code>verbose</code>     | <code>logical</code> or non-negative integer indicating if and how much of the compression utilities' output should be shown.                                                                                                                                      |
| <code>x</code>           | An object of class "compactPDF".                                                                                                                                                                                                                                   |
| <code>ratio, diff</code> | Limits for reporting: files are only reported whose sizes are reduced both by a factor of <code>ratio</code> and by <code>diff</code> bytes.                                                                                                                       |
| <code>...</code>         | Further arguments to be passed to or from other methods.                                                                                                                                                                                                           |

### Details

This by default makes use of qpdf, available from <https://qpdf.sourceforge.io/> (including as a Windows binary) and included with the CRAN macOS distribution of R. If `gs_cmd` is non-empty and `gs_quality != "none"`, GhostScript will be used first, then qpdf if it is available. If `gs_quality != "none"` and `gs_cmd` is "", an attempt will be made to find a GhostScript executable.

qpdf and/or `gs_cmd` are run on all PDF files found, and those which are reduced in size by at least 10% and 10Kb are replaced.

The strategy of our use of qpdf is to (losslessly) compress both PDF streams and objects. GhostScript compresses streams and more (including downsampling and compressing embedded images) and consequently is much slower and may lose quality (but can also produce much smaller PDF files). However, quality "ebook" is perfectly adequate for screen viewing and printing on laser printers.

Where PDF files are changed they will become PDF version 1.5 files: these have been supported by Acrobat Reader since version 6 in 2003, so this is very unlikely to cause difficulties.

Stream compression is what most often has large gains. Most PDF documents are generated with object compression, but this does not seem to be the default for MiKTeX's pdf<sub>l</sub>atex. For some PDF files (and especially package vignettes), using GhostScript can dramatically reduce the space taken by embedded images (often screenshots).

Where both GhostScript and qpdf are selected (when `gs_quality != "none"` and both executables are found), they are run in that order and the size reductions apply to the total compression achieved.

### Value

An object of class `c("compactPDF", "data.frame")`. This has two columns, the old and new sizes in bytes for the files that were changed.

There are `format` and `print` methods: the latter passes `...` to the `format` method, so will accept `ratio` and `diff` arguments.

### Note

The external tools used may change in future releases.

Frequently, updates to GhostScript have produced better compression (up to several times better), so if possible use the latest version available.

CRANtools

*CRAN Package Repository Tools*

---

**Description**

Tools for obtaining information about current and archived packages in the CRAN package repository, and the check status of the current packages.

**Usage**

```
CRAN_package_db()

CRAN_check_results(flavors = NULL)
CRAN_check_details(flavors = NULL)
CRAN_check_issues()
summarize_CRAN_check_status(packages,
                             results = NULL,
                             details = NULL,
                             issues = NULL)

CRAN_current_db()
CRAN_aliases_db()
CRAN_rdxrefs_db()
CRAN_archive_db()

CRAN_authors_db()
```

**Arguments**

|                       |                                                                                                                        |
|-----------------------|------------------------------------------------------------------------------------------------------------------------|
| <code>packages</code> | a character vector of package names.                                                                                   |
| <code>flavors</code>  | a character vector of CRAN check flavor names, or <code>NULL</code> (default), corresponding to all available flavors. |
| <code>results</code>  | the return value of <code>CRAN_check_results()</code> (default), or a subset of this.                                  |
| <code>details</code>  | the return value of <code>CRAN_check_details()</code> (default), or a subset of this.                                  |
| <code>issues</code>   | the return value of <code>CRAN_check_issues()</code> (default), or a subset of this.                                   |

**Details**

`CRAN_package_db()` returns a data frame with character columns containing most ‘DESCRIPTION’ metadata for the current packages in the CRAN package repository, including in particular the Description and Maintainer information not provided by `utils::available.packages()`.

`CRAN_check_results()` returns a data frame with the basic CRAN package check results including timings, with columns `Package`, `Flavor` and `Status` giving the package name, check flavor, and overall check status, respectively.

`CRAN_check_details()` returns a data frame inheriting from class "check\_details" (which has useful print and format methods) with details on the check results, providing check name, status and output for every non-OK check (*via* columns `Check`, `Status` and `Output`, respectively). Packages with all-OK checks are indicated via a \* Check wildcard name and OK Status.

`CRAN_check_issues()` returns a information on additional check issues (including the memory-access check results made available from <https://www.stats.ox.ac.uk/pub/bdr/memtests/>) as a data frame with character variables `Package`, `Version`, `kind` (an identifier for the issue) and `href` (a URL with information on the issue).

`CRAN_current_db()` returns a data frame with the `file.info()` of all current package sources in the CRAN package repository.

`CRAN_aliases_db()` returns the Rd aliases in the current packages, as a nested per-package named list of per-Rd-file named lists with the aliases.

`CRAN_rdxrefs_db()` returns the Rd cross-references in the current packages, as a per-package list of matrices with columns "Target", "Anchor" and "Source".

`CRAN_archive_db()` returns the `file.info()` of all archived packages sources in the CRAN package repository, as a per-package named list of data frames.

`CRAN_authors_db()` returns information on the authors of the current CRAN packages extracted from the 'Authors@R' fields in the package 'DESCRIPTION' files, as a data frame with character columns giving the given and family names, email addresses, roles, comments, ORCID and ROR identifiers of the person entries, and the corresponding package.

## Value

See 'Details'. Note that the results are collated on CRAN: currently this is done in a locale which sorts aAbB ....

## Which CRAN?

Functions `CRAN_package_db()`, `CRAN_check_results()`, `CRAN_check_details()` and `CRAN_check_issues()` access a CRAN mirror specified by the environment variable `R_CRAN_WEB`, defaulting to one specified in the "repos" option. Otherwise the entry in the 'repositories' file (see [setRepositories](#)) is used: if that specifies '@CRAN@' (the default) or does not contain an entry for CRAN then <https://CRAN.R-project.org> is used.

The mirror to be used is reported by `utils::findCRANmirror("web")`.

Note that these functions access parts of CRAN under 'web/contrib' and 'web/packages' so if you have specified a mirror of just 'src/contrib' for installing packages you will need to set `R_CRAN_WEB` to point to a full mirror.

Functions `CRAN_current_db()`, `CRAN_aliases_db()`, `CRAN_rdxrefs_db()`, `CRAN_authors_db()` and `CRAN_archive_db()` (also used by R CMD check) use `R_CRAN_SRC` rather than `R_CRAN_WEB`. The mirror to be used is reported by `utils::findCRANmirror("src")`.

## See Also

[base\\_aliases\\_db\(\)](#) and [base\\_rdxrefs\\_db\(\)](#) for getting the Rd aliases and cross-references in the base packages.

## Examples

```
## This can be rather slow with a non-local CRAN mirror
## and might fail (slowly) without Internet access in that case.
```

```

set.seed(11) # but the packages chosen will change as soon as CRAN does.

```

---

delimMatch

*Delimited Pattern Matching*

---

## Description

Match delimited substrings in a character vector, with proper nesting.

## Usage

```
delimMatch(x, delim = c("{", "}"), syntax = "Rd")
```

**Arguments**

|                     |                                                                                                                                                                                                                                                                                         |
|---------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>      | a character vector.                                                                                                                                                                                                                                                                     |
| <code>delim</code>  | a character vector of length 2 giving the start and end delimiters. Future versions might allow for arbitrary regular expressions.                                                                                                                                                      |
| <code>syntax</code> | currently, always the string "Rd" indicating Rd syntax (i.e., '%' starts a comment extending till the end of the line, and '\' escapes). Future versions might know about other syntax, perhaps via 'syntax tables' allowing to flexibly specify comment, escape, and quote characters. |

**Value**

An integer vector of the same length as `x` giving the starting position (in characters) of the first match, or `-1` if there is none, with attribute `"match.length"` giving the length (in characters) of the matched text (or `-1` for no match).

**See Also**

[regexpr](#) for 'simple' pattern matching.

**Examples**

```
x <- c("\\value{foo}", "function(bar)")
delimMatch(x)
delimMatch(x, c("(", ")"))
```

---

dependsOnPkgs

*Find Reverse Dependencies*

---

**Description**

Find 'reverse' dependencies of packages, that is those packages which depend on this one, and (optionally) so on recursively.

**Usage**

```
dependsOnPkgs(pkgs,
              dependencies = "strong",
              recursive = TRUE, lib.loc = NULL,
              installed =
                utils::installed.packages(lib.loc, fields = "Enhances"))
```

**Arguments**

|                           |                                                                                                                                                                                                                                                                                                                                                     |
|---------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>pkgs</code>         | a character vector of package names.                                                                                                                                                                                                                                                                                                                |
| <code>dependencies</code> | a character vector listing the types of dependencies, a subset of <code>c("Depends", "Imports", "LinkingTo", "Suggests", "Enhances")</code> . Character string "all" is shorthand for that vector, character string "most" for the same vector without "Enhances", character string "strong" (default) for the first three elements of that vector. |
| <code>recursive</code>    | logical: should reverse dependencies of reverse dependencies (and so on) be included?                                                                                                                                                                                                                                                               |

`lib.loc` a character vector of R library trees, or NULL for all known trees (see [.libPaths\(\)](#)).

`installed` a result of calling [installed.packages\(\)](#).

### Value

A character vector of package names, which does not include any from pkgs.

### See Also

[package\\_dependencies\(\)](#) to get the regular (“forward”) dependencies of a package.

### Examples

```
## there are few dependencies in a vanilla R installation:
## lattice may not be installed
dependsOnPkgs("lattice")
```

---

|          |                           |
|----------|---------------------------|
| doitools | <i>Check Package DOIs</i> |
|----------|---------------------------|

---

### Description

Check DOIs in package sources.

### Usage

```
check_package_dois(dir, verbose = FALSE)
```

### Arguments

`dir` a character string specifying the path to a package’s root source directory.

`verbose` a logical indicating if output should monitor check progress.

### Details

Checking DOIs is performed in parallel using **curl** (so this must be installed for checking).

The DOIs checked are extracted from the package ‘DESCRIPTION’ (<doi:...> URIs in the ‘Description’ field), Rd and ‘CITATION’ files.

The DOIs are checked via ‘HEAD’ requests to the DOI system Proxy Server REST API.

### Value

A data frame inheriting from class `check_doi_db` with information on the DOI check problems found.

### Note

This functionality is still experimental: interfaces may change in future versions.

---

encoded\_text\_to\_latex *Translate non-ASCII Text to LaTeX Escapes*

---

## Description

Translate non-ASCII characters in text to LaTeX escape sequences.

## Usage

```
encoded_text_to_latex(x,  
                      encoding = c("latin1", "latin2", "latin9",  
                                   "UTF-8", "utf8"))
```

## Arguments

|          |                                                                                                                             |
|----------|-----------------------------------------------------------------------------------------------------------------------------|
| x        | a character vector.                                                                                                         |
| encoding | the encoding to be assumed. "latin9" is officially ISO-8859-15 or Latin-9, but known as latin9 to LaTeX's inputenc package. |

## Details

Non-ASCII characters in x are replaced by an appropriate LaTeX escape sequence, or '?' if there is no appropriate sequence.

Even if there is an appropriate sequence, it may not be supported by the font in use. Hyphen is mapped to '\-'.

## Value

A character vector of the same length as x.

## See Also

[iconv](#)

## Examples

```
x <- "fran\xE7ais"  
encoded_text_to_latex(x, "latin1")  
## Not run:  
## create a tex file to show the upper half of 8-bit charsets  
x <- rawToChar(as.raw(160:255), multiple = TRUE)  
(x <- matrix(x, ncol = 16, byrow = TRUE))  
xx <- x  
xx[] <- encoded_text_to_latex(x, "latin1") # or latin2 or latin9  
xx <- apply(xx, 1, paste, collapse = "&")  
con <- file("test-encoding.tex", "w")  
header <- c(  
  "\\documentclass{article}",  
  "\\usepackage[T1]{fontenc}",  
  "\\usepackage{Rd}",  
  "\\begin{document}",  
  "\\HeaderA{test}{}{test}",
```

```

"\\begin{Details}\\relax",
"\\Tabular{cccccccccccccc}{")
trailer <- c(")", "\\end{Details}", "\\end{document}")
writelines(header, con)
writelines(paste0(xx, "\\\""), con)
writelines(trailer, con)
close(con)
## and some UTF_8 chars
x <- intToUtf8(as.integer(
  c(160:383, 0x0192, 0x02C6, 0x02C7, 0x02CA, 0x02D8,
    0x02D9, 0x02DD, 0x200C, 0x2018, 0x2019, 0x201C,
    0x201D, 0x2020, 0x2022, 0x2026, 0x20AC)),
  multiple = TRUE)
x <- matrix(x, ncol = 16, byrow = TRUE)
xx <- x
xx[] <- encoded_text_to_latex(x, "UTF-8")
xx <- apply(xx, 1, paste, collapse = "&")
con <- file("test-utf8.tex", "w")
writelines(header, con)
writelines(paste(xx, "\\\" ", sep = " "), con)
writelines(trailer, con)
close(con)

## End(Not run)

```

fileutils

*File Utilities***Description**

Utilities for listing files, and manipulating file paths.

**Usage**

```

file_ext(x)
file_path_as_absolute(x)
file_path_sans_ext(x, compression = FALSE)

list_files_with_exts(dir, exts, all.files = FALSE,
  full.names = TRUE)
list_files_with_type(dir, type, all.files = FALSE,
  full.names = TRUE, OS_subdirs = .OSType())

```

**Arguments**

|             |                                                                                                |
|-------------|------------------------------------------------------------------------------------------------|
| x           | character vector giving file paths.                                                            |
| compression | logical: should compression extension ‘.gz’, ‘.bz2’ or ‘.xz’ be removed first?                 |
| dir         | a character string with the path name to a directory.                                          |
| exts        | a character vector of possible file extensions (excluding the leading dot).                    |
| all.files   | a logical. If FALSE (default), only visible files are considered; if TRUE, all files are used. |

|            |                                                                                                                                                                                                                                                                                |
|------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| full.names | a logical indicating whether the full paths of the files found are returned (default), or just the file names.                                                                                                                                                                 |
| type       | a character string giving the ‘type’ of the files to be listed, as characterized by their extensions. Currently, possible values are "code" (R code), "data" (data sets), "demo" (demos), "docs" (R documentation), and "vignette" (vignettes).                                |
| OS_subdirs | a character vector with the names of OS-specific subdirectories to possibly include in the listing of R code and documentation files. By default, the value of the environment variable R_OSTYPE, or if this is empty, the value of <code>.Platform\$OS.type</code> , is used. |

### Details

`file_ext` returns the file (name) extensions (excluding the leading dot). (Only purely alphanumeric extensions are recognized.)

`file_path_as_absolute` turns a possibly relative file path absolute, performing tilde expansion if necessary. This is a wrapper for `normalizePath`. Currently, `x` must be a single existing path.

`file_path_sans_ext` returns the file paths without extensions (and the leading dot). (Only purely alphanumeric extensions are recognized.)

`list_files_with_exts` returns the paths or names of the files in directory `dir` with extension matching one of the elements of `exts`. Note that by default, full paths are returned, and that only visible files are used.

`list_files_with_type` returns the paths of the files in `dir` of the given ‘type’, as determined by the extensions recognized by R. When listing R code and documentation files, files in OS-specific subdirectories are included if present according to the value of `OS_subdirs`. Note that by default, full paths are returned, and that only visible files are used.

### See Also

`file.path`, `file.info`, `list.files`

### Examples

```
dir <- file.path(R.home(), "library", "stats")
list_files_with_exts(file.path(dir, "demo"), "R")
list_files_with_type(file.path(dir, "demo"), "demo") # the same
file_path_sans_ext(list.files(file.path(R.home("modules"))))
```

---

find\_gs\_cmd

*Find a GhostScript Executable*

---

### Description

Find a GhostScript executable in a cross-platform way.

### Usage

```
find_gs_cmd(gs_cmd = "")
```

### Arguments

`gs_cmd`                      The name, full or partial path of a GhostScript executable.

## Details

The details differ by platform.

On a Unix-alike, the GhostScript executable is usually called gs. The name (and possibly path) of the command is taken first from argument `gs_cmd` then from the environment variable `R_GSCMD` and default `gs`. This is then looked for on the system path and the value returned if a match is found.

On Windows, the name of the command is taken from argument `gs_cmd` then from the environment variables `R_GSCMD` and `GSC`. If neither of those produces a suitable command name, `gswin64c` and `gswin32c` are tried in turn. In all cases the command is looked for on the system `PATH`.

Note that on Windows (and some other OSes) there are separate GhostScript executables to display Postscript/PDF files and to manipulate them: this function looks for the latter.

## Value

A character string giving the full path to a GhostScript executable if one was found, otherwise an empty string.

## Examples

```
## Not run:
## Suppose a Solaris system has GhostScript 9.00 on the path and
## 9.07 in /opt/csw/bin. Then one might set
Sys.setenv(R_GSCMD = "/opt/csw/bin/gs")

## End(Not run)
```

---

getVignetteInfo

*Get Information on Installed Vignettes*

---

## Description

This function gets information on installed vignettes.

## Usage

```
getVignetteInfo(package = NULL, lib.loc = NULL, all = TRUE)
```

## Arguments

|                      |                                                                      |
|----------------------|----------------------------------------------------------------------|
| <code>package</code> | Which package to look in, or <code>NULL</code> for all packages.     |
| <code>lib.loc</code> | Which library to look in.                                            |
| <code>all</code>     | Whether to search all installed packages, or just attached packages. |

## Value

A matrix with columns

|                      |                                                 |
|----------------------|-------------------------------------------------|
| <code>Package</code> | the name of the package                         |
| <code>Dir</code>     | the directory where the package is installed    |
| <code>Topic</code>   | the name of the vignette                        |
| <code>File</code>    | the base filename of the source of the vignette |

|       |                                        |
|-------|----------------------------------------|
| Title | the title of the vignette              |
| R     | the tangled R source from the vignette |
| PDF   | the PDF or HTML file for display       |

**Note**

The last column of the result is named PDF for historical reasons, but it may contain a filename of a PDF or HTML document.

**See Also**

[pkgVignettes](#) is a similar function that can work on an uninstalled package.

**Examples**

```
getVignetteInfo("grid")
```

---

HTMLheader

---

*Generate a Standard HTML Header for R Help*

---

**Description**

This function generates the standard HTML header used on R help pages.

**Usage**

```
HTMLheader(title = "R", logo = TRUE, up = NULL,
            top = file.path(Rhome, "doc/html/index.html"),
            Rhome = "",
            css = file.path(Rhome, "doc/html/R.css"),
            headerTitle = paste("R:", title),
            outputEncoding = "UTF-8")
```

**Arguments**

|                |                                                                                                   |
|----------------|---------------------------------------------------------------------------------------------------|
| title          | The title to display and use in the HTML headers. Should have had any HTML escaping already done. |
| logo           | Whether to display the R logo after the title.                                                    |
| up             | Which page (if any) to link to on the “up” button.                                                |
| top            | Which page (if any) to link to on the “top” button.                                               |
| Rhome          | A <b>relative</b> path to the R home directory. See the ‘Details’.                                |
| css            | The relative URL for the Cascading Style Sheet.                                                   |
| headerTitle    | The title used in the headers.                                                                    |
| outputEncoding | The declared encoding for the whole page.                                                         |

**Details**

The up and top links should be relative to the current page. The Rhome path default works with dynamic help; for static help, a relative path (e.g., ‘../.’) to it should be used.

**Value**

A character vector containing the lines of an HTML header which can be used to start a page in the R help system.

**Examples**

```
cat(HTMLheader("This is a sample header"), sep="\n")
```

HTMLlinks

*Collect HTML Links from Package Documentation***Description**

Compute relative file paths for URLs to other package's installed HTML documentation.

**Usage**

```
findHTMLlinks(pkgDir = "", lib.loc = NULL, level = 0:3)
```

**Arguments**

|                      |                                                                                                                       |
|----------------------|-----------------------------------------------------------------------------------------------------------------------|
| <code>pkgDir</code>  | the top-level directory of an installed package. The default indicates no package.                                    |
| <code>lib.loc</code> | character vector describing the location of R library trees to scan: the default indicates <code>.libPaths()</code> . |
| <code>level</code>   | Which level(s) to include.                                                                                            |

**Details**

`findHTMLlinks` tries to resolve links from one help page to another. It uses in decreasing priority

- The package in `pkgDir`: this is used when converting HTML help for that package (level 0).
- The base and recommended packages (levels 1 and 2).
- Other packages found in the library trees specified by `lib.loc` in the order of the trees and alphabetically within a library tree (level 3).

**Value**

A named character vector of file paths, relative to the 'html' directory of an installed package. So these are of the form `"../.. /somepkg/html/sometopic.html"`.

**Author(s)**

Duncan Murdoch, Brian Ripley

licensetools

*License Tools***Description**

Tools for computing on license specifications.

**Usage**

```
analyze_license(x)
```

**Arguments**

`x` a character string.

**Details**

R packages use the ‘License’ field in their ‘DESCRIPTION’ file to specify their license in a standardized form described in section ‘Licenses’ of the ‘Writing R Extensions’ manual. This uses alternatives of individual specifications (‘components’) which can use version restrictions or give pointers to ‘LICENSE’ (or ‘LICENCE’) files either restricting the base license or giving a full license.

Function `analyze_license()` checks if a given character string provides such a standardized license spec (or something recognized as a historic exception which can be transformed to a standardized spec). If standardizable, it extracts the individual components and where these give version ranges the corresponding expansions into components with fixed versions. It also indicates whether the license can be verified to be FOSS ([https://en.wikipedia.org/wiki/Free\\_and\\_open-source\\_software](https://en.wikipedia.org/wiki/Free_and_open-source_software)) licenses and where possible computes an **SPDX license identifier** for the license.

**Value**

a list with elements including

`is_canonical` a logical indicating whether the given string is a standardized license spec.

`is_standardizable`

a logical indicating whether the given string is a standardized license spec, or can be transformed to one.

`standardization`

a character string giving the standardized license spec corresponding to the given string if this is standardizable.

`components` the components of the standardized license spec.

`expansions` the expansions of the components of the standardized license spec.

`is_verified` a logical indicating whether the given string can be verified to specify a FOSS license.

`spdx` an SPDX license identifier for the license spec.

## Examples

```
## Examples from section 'Licenses' of 'Writing R Extensions':
analyze_license("GPL-2")
analyze_license("LGPL (>= 2.0, < 3) | Mozilla Public License")
analyze_license("GPL-2 | file LICENCE")
analyze_license("GPL (>= 2) | BSD_3_clause + file LICENSE")
analyze_license("Artistic-2.0 | AGPL-3 + file LICENSE")
```

---

loadRdMacros

*Load User-defined Rd Help System Macros*

---

## Description

Loads macros from an ‘.Rd’ file, or from several ‘.Rd’ files contained in a package.

## Usage

```
loadRdMacros(file, macros = TRUE)
loadPkgRdMacros(pkgdir, macros = NULL)
```

## Arguments

|        |                                                                                                                                                                                 |
|--------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| file   | A file in Rd format containing macro definitions.                                                                                                                               |
| macros | optionally, a previous set of macro definitions, in the format expected by the <a href="#">parse_Rd</a> macros argument. loadPkgRdMacros loads the system Rd macros by default. |
| pkgdir | The base directory of a source package or an installed package.                                                                                                                 |

## Details

The Rd files parsed by these functions should contain only macro definitions; a warning will be issued if anything else other than comments or white space is found.

The macros argument may be a filename of a base set of macros, or the result of a previous call to loadRdMacros or loadPkgRdMacros in the same session. These results should be assumed to be valid only within the current session.

The loadPkgRdMacros function first looks for an “RdMacros” entry in the package ‘DESCRIPTION’ file. If present, it should contain a comma-separated list of other package names; their macros will be loaded before those of the current package. It will then look in the current package for ‘.Rd’ files in the ‘man/macros’ or ‘help/macros’ subdirectories, and load those.

## Value

These functions each return an environment containing objects with the names of the newly defined macros from the last file processed. The parent environment will be macros from the previous file, and so on. The first file processed will have [emptyenv\(\)](#) as its parent.

## Author(s)

Duncan Murdoch

\newcommand{\Rlogo}{
  \if{html}{\figure{Rlogo.svg}{options: width=100 alt="R logo"}}
  \if{latex}{\figure{Rlogo.pdf}{options: width=0.5in}}
}
)", f)
m <- loadRdMacros(f)
ls(m)
ls(parent.env(m))
ls(parent.env(parent.env(m)))
parse_Rd(textConnection(r"(\Rlogo)"), fragment = TRUE, macros = m)
```

---

makevars

*User and Site Compilation Variables*

---

## Description

Determine the location of the user and site specific ‘Makevars’ files for customizing package compilation.

## Usage

```
makevars_user()
makevars_site()
```

## Details

Package maintainers can use these functions to employ user and site specific compilation settings also for compilations not using R’s mechanisms (in particular, custom compilations in subdirectories of ‘src’), e.g., by adding configure code calling R with `cat(tools::makevars_user())` or `cat(tools::makevars_site())`, and if non-empty passing this with ‘-f’ to custom Make invocations.

## Value

A character string with the path to the user or site specific ‘Makevars’ file, or an empty character vector if there is no such file.

## See Also

Section ‘Customizing package compilation’ in the ‘R Installation and Administration’ manual.

## Examples

```
makevars_user()
makevars_site()
```

---

make\_translations\_pkg *Package the Current Translations in the R Sources*

---

## Description

A utility for R Core members to prepare a package of updated translations.

## Usage

```
make_translations_pkg(srcdir, outDir = ".", append = "-1")
```

## Arguments

|        |                                                                                           |
|--------|-------------------------------------------------------------------------------------------|
| srcdir | The R source directory.                                                                   |
| outDir | The directory into which to place the prepared package.                                   |
| append | The suffix for the package version number, e.g. ‘3.0.0-1’ will be the default in R 3.0.0. |

## Details

This extracts the translations in a current R source distribution and packages them as a source package called **translations** which can be distributed on CRAN and installed by [update.packages](#). This allows e.g. the translations shipped in R 3.x.y to be updated to those currently in ‘R-patched’, even by a user without administrative privileges.

The package has a ‘Depends’ field which restricts it to versions ‘3.x.\*’ for a single x.

---

|                  |                                                    |
|------------------|----------------------------------------------------|
| matchConcordance | <i>Concordance between source and target lines</i> |
|------------------|----------------------------------------------------|

---

## Description

The Rd parser records locations in ‘.Rd’ files from which components of the file are read. Output generators [Rd2HTML](#) and [Rd2latex](#) can output information about these locations as “concordances” between source and output lines.

matchConcordance converts from output locations to source locations. The “Rconcordance” method of as.character produces strings to embed in output files, and the default method of as.Rconcordance converts these back to objects that can be interpreted by matchConcordance.

## Usage

```
matchConcordance(linenum, concordance)
## S3 method for class 'Rconcordance'
as.character(x, targetfile = "", ...)
as.Rconcordance(x, ...)
followConcordance(concordance, prevConcordance)
```

## Arguments

|                 |                                                                                                                                                                                                               |
|-----------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| linenum         | One or more line numbers being queried.                                                                                                                                                                       |
| concordance     | The concordance data for the file containing the lines: an object of class "Rconcordance".                                                                                                                    |
| prevConcordance | A concordance object retrieved from the current file.                                                                                                                                                         |
| targetfile      | The output filename.                                                                                                                                                                                          |
| x               | The object to convert: for <code>as.character</code> , an "Rconcordance" object; for <code>as.concordance</code> , a character vector which contains <code>as.character</code> output, typically in comments. |
| ...             | Further arguments passed to other methods.                                                                                                                                                                    |

## Details

The correspondence between target lines and source lines in Rd file conversion is not one to one. Often a single source line can lead to the generation of multiple output lines, and sometimes more than one source line triggers output on the same output line.

`matchConcordance` converts from target lines to source lines. This can be used to help in understanding how particular output lines depend on the source, e.g. when an error is found in the output file. When more than one line contributes to the output, the last one will be returned.

The "Rconcordance" method of `as.character` converts a concordance object to strings suitable for embedding (e.g. in comments) in an output file.

The default method of `as.Rconcordance` searches for strings matching the pattern of `as.character.Rconcordance` output, then converts those lines back to a single concordance.

`followConcordance` is used when a file is transformed more than once. The first transformation records a concordance in the file which is read as `prevConcordance`. `followConcordance` chains this with the current concordance, relating the final result to the original source.

There are 3 kinds of objects used to hold concordances.

Objects of class "activeConcordance" are internal to **tools**; they are used by `Rd2HTML` and `Rd2latex` while building the output file and saving links to the source file.

Objects of class "Rconcordance" are visible to users. They are list objects with the following three fields:

|         |                                                                                                                                                                                                                                        |
|---------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| offset  | The number of lines of output before the first one corresponding to this concordance.                                                                                                                                                  |
| srcLine | For each line of output after the offset, the corresponding input file line number. There may be more lines of output than the length of <code>srcLine</code> , in which case nothing can be inferred about the source of those lines. |
| srcFile | A vector of filenames of length 1 or the same length as <code>srcLine</code> giving the source file(s) for each output line.                                                                                                           |

Concordance strings are produced by the "Rconcordance" method of `as.character`; they are simply character vectors encoding the concordance data. The default method of the `as.concordance` generic function converts them to "Rconcordance" objects.

**Value**

matchConcordance returns a character array with one row per input linenum entry and two columns, "srcFile" and "srcLine".

For the "Rconcordance" method of as.character, a character vector used (e.g. in [Sweave](#)) to embed the concordance in a file.

For as.concordance, an "Rconcordance" object, or NULL if no concordance strings are found.

---

|        |                              |
|--------|------------------------------|
| md5sum | <i>Compute MD5 Checksums</i> |
|--------|------------------------------|

---

**Description**

Compute the 32-byte MD5 hashes of one or more files, or a raw vector of bytes.

**Usage**

```
md5sum(files, bytes)
```

**Arguments**

|       |                                                                      |
|-------|----------------------------------------------------------------------|
| files | character. The paths of file(s) whose contents are to be hashed.     |
| bytes | raw. Bytes to be hashed. NB: bytes and files are mutually exclusive. |

**Details**

A MD5 'hash' or 'checksum' or 'message digest' is a 128-bit summary of the file contents represented by 32 hexadecimal digits. Files with different MD5 sums are different: only very exceptionally (and usually with the intent to deceive) are those with the same sums different.

On Windows all files are read in binary mode (as the md5sum utilities there do): on other OSes the files are read in the default mode (almost always text mode where there is more than one).

MD5 sums are used as a check that R packages have been unpacked correctly and not subsequently accidentally modified.

**Value**

If used with files, a character vector of the same length as files, with names equal to files (possibly expanded). The elements will be NA for non-existent or unreadable files, otherwise a 32-character string of hexadecimal digits.

For bytes the result is a single 32-character string.

**Source**

The underlying C code was written by Ulrich Drepper and extracted from a 2001 release of glibc.

**See Also**

[checkMD5sums](#), [sha256sum](#)

**Examples**

```
as.vector(md5sum(dir(R.home(), pattern = "^COPY", full.names = TRUE)))
md5sum(bytes=raw())
md5sum(bytes=charToRaw("abc"))
```

---

package\_dependencies    *Computations on the Dependency Hierarchy of Packages*

---

**Description**

Find (recursively) dependencies or reverse dependencies of packages.

**Usage**

```
package_dependencies(packages = NULL, db = NULL, which = "strong",
  recursive = FALSE, reverse = FALSE,
  verbose = getOption("verbose"))
```

**Arguments**

|           |                                                                                                                                                                                                                                                                                                                                        |
|-----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| packages  | a character vector of package names.                                                                                                                                                                                                                                                                                                   |
| db        | character matrix as from <a href="#">available.packages()</a> (with the default NULL the results of this call) or data frame variants thereof. Alternatively, a package database like the one available from <a href="https://cran.r-project.org/web/packages/packages.rds">https://cran.r-project.org/web/packages/packages.rds</a> . |
| which     | a character vector listing the types of dependencies, a subset of c("Depends", "Imports", "LinkingTo", "Suggests", "Enhances"). Character string "all" is shorthand for that vector, character string "most" for the same vector without "Enhances", character string "strong" (default) for the first three elements of that vector.  |
| recursive | a logical indicating whether (reverse) dependencies of (reverse) dependencies (and so on) should be included, or a character vector like which indicating the type of (reverse) dependencies to be added recursively.                                                                                                                  |
| reverse   | logical: if FALSE (default), regular dependencies are calculated, otherwise reverse dependencies.                                                                                                                                                                                                                                      |
| verbose   | logical indicating if output should monitor the package search cycles.                                                                                                                                                                                                                                                                 |

**Value**

Named list with one element for each package in argument packages, each consists of a character vector naming the (recursive) (reverse) dependencies of that package.

For given packages which are not found in the db, NULL entries are returned, as opposed to character(0) entries which indicate no dependencies.

**See Also**

[dependsOnPkgs.](#)

**Examples**

```
myPkgs <- c("MASS", "Matrix", "KernSmooth", "class", "cluster", "codetools")
pdb <- available.packages(repos = findCRANmirror("web"))
system.time(
  dep1 <- package_dependencies(myPkgs, db = pdb) # all arguments at default
) # very fast
utils::str(dep1, vec.len=10)

system.time( ## reverse dependencies, recursively --- takes much longer:
  deps <- package_dependencies(myPkgs, db = pdb, which = "most",
                             recursive = TRUE, reverse = TRUE)
) # seen ~ 10 seconds

lengths(deps) # 2020-05-03: all are 16053, but codetools with 16057

## install.packages(dependencies = TRUE) installs 'most' dependencies
## and the strong recursive dependencies of these: these dependencies
## can be obtained using 'which = "most"' and 'recursive = "strong"'.
## To illustrate on the first packages with non-missing Suggests:
packages <- pdb[head(which(!is.na(pdb[, "Suggests"]))), "Package"]
package_dependencies(packages, db = pdb,
                    which = "most", recursive = "strong")
```

---

package\_native\_routine\_registration\_skeleton

*Write Skeleton for Adding Native Routine Registration to a Package*

---

**Description**

Write a skeleton for adding native routine registration to a package.

**Usage**

```
package_native_routine_registration_skeleton(dir, con = stdout(),
  align = TRUE, character_only = TRUE, include_declarations = TRUE)
```

**Arguments**

|                                   |                                                                                                                                                |
|-----------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>dir</code>                  | Top-level directory of a package.                                                                                                              |
| <code>con</code>                  | Connection on which to write the skeleton: can be specified as a file path.                                                                    |
| <code>align</code>                | Logical: should the registration tables be lined up in three columns each?                                                                     |
| <code>character_only</code>       | Logical: should only <code>.NAME</code> arguments specified by character strings (and not as names of R objects nor expressions) be extracted? |
| <code>include_declarations</code> | Logical: should the output include declarations (also known as ‘prototypes’) for the registered routines?                                      |

## Details

Registration is described in section ‘Registering native routines’ of ‘Writing R Extensions’. This function produces a skeleton of the C code which needs to be added to enable registration, conventionally as file ‘src/init.c’ or appended to the sole C file of the package.

This function examines the code in the ‘R’ directory of the package for calls to `.C`, `.Fortran`, `.Call` and `.External` and creates registration information for those it can make sense of. If the number of arguments used cannot be determined it will be recorded as `-1`: such values should be corrected.

Optionally the skeleton will include declarations for the registered routines: they should be checked against the C/Fortran source code, not least as the number of arguments is taken from the R code. For `.Call` and `.External` calls they will often suffice, but for `.C` and `.Fortran` calls the ‘void \*’ arguments would ideally be replaced by the actual types. Otherwise declarations need to be included (they may exist earlier in that file if appending to a file, or in a header file which can be included in ‘init.c’).

The default value of `character_only` is appropriate when working on a package without any existing registration: `character_only = FALSE` can be used to suggest updates for a package which has been extended since registration. For the default value, if `.NAME` values are found which are not character strings (e.g. names or expressions) this is noted via a comment in the output.

Packages which used the earlier form of creating R objects for native symbols *via* additional arguments in a `useDynLib` directive will probably most easily be updated to use registration with `character_only = FALSE`.

If an entry point is used with different numbers of arguments in the package’s R code, an entry in the table (and optionally, a declaration) is made for each number, and a comment placed in the output. This needs to be resolved: only `.External` calls can have a variable number of arguments, which should be declared as `-1`.

A surprising number of CRAN packages had calls in R code to native routines not included in the package, which will lead to a ‘loading failed’ error during package installation when the registration C code is added.

Calls which do not name a routine such as `.Call(...)` will be silently ignored.

## Value

None: the output is written to the connection `con`.

## Extracting C/C++ prototypes

There are several tools available to extract function declarations from C or C++ code.

For C code one can use `cproto` (<https://invisible-island.net/cproto/cproto.html>; Windows executables are available), for example

```
cproto -I/path/to/R/include -e *.c
```

`ctags` (commonly distributed with the OS) covers C and C++, using something like

```
ctags -x *.c
```

to list all function usages. (The ‘Exuberant’ version allows a lot more control.)

## Extracting Fortran prototypes

gfortran 9.2 and later can extract C prototypes for Fortran subroutines with a special flag:

```
gfortran -c -fc-prototypes-external file.f
```

although ironically not for functions declared `bind(C)`.

## Note

This only examines the 'R' directory: it will not find e.g. `.Call` calls used directly in examples, tests *etc.*

Static code analysis is used to find the `.C` etc calls: it *will* find those in parts of the R code 'commented out' by inclusion in `if(FALSE) { ... }`. On the other hand, it will fail to find the entry points in constructs like

```
.Call(if(int) "rle_i" else "rle_d", i, force)
```

and does not know the value of variables in calls like

```
.Call (cfunction, ...)
.Call(..., PACKAGE="sparseLTSEigen")
```

(but if `character_only` is false, will extract the first as `"cfunction"`). Calls which have not been fully resolved will be noted *via* comments in the output file.

Call to entry points in other packages will be ignored if they have an explicit (character string) `PACKAGE` argument.

```

---

parseLatex

---

*Experimental Functions to Work with LaTeX Code*

---

## Description

The `parseLatex` function parses LaTeX source, producing a structured object; `deparseLatex` reverses the process. The `latexToUtf8` function takes a LaTeX object, and processes a number of different macros to convert them into the corresponding UTF-8 characters.

## Usage

```

parseLatex(text, filename = "text",
           verbose = FALSE,
           verbatim = c("verbatim", "verbatim*",
                        "Sinput", "Soutput"),
           verb = "\\Sexpr",
           defcmd = c("\\newcommand", "\\renewcommand",
                     "\\providecommand", "\\def", "\\let"),
           defenv = c("\\newenvironment",
                     "\\renewenvironment"))
deparseLatex(x, dropBraces = FALSE)
latexToUtf8(x)

```

## Arguments

|                                           |                                                                                                                 |
|-------------------------------------------|-----------------------------------------------------------------------------------------------------------------|
| <code>text</code>                         | A character vector containing LaTeX source code.                                                                |
| <code>filename</code>                     | No longer used.                                                                                                 |
| <code>verbose</code>                      | If TRUE, print debug error messages.                                                                            |
| <code>verbatim</code>                     | A character vector containing the names of LaTeX environments holding verbatim text.                            |
| <code>verb</code>                         | A character vector containing LaTeX macros that should be assumed to hold verbatim text.                        |
| <code>defcmd</code> , <code>defenv</code> | Character vectors containing LaTeX macros that should be assumed to define macros or environments respectively. |
| <code>x</code>                            | A "LaTeX" object.                                                                                               |
| <code>dropBraces</code>                   | Drop unnecessary braces when displaying a "LaTeX" object.                                                       |

## Details

The parser does not recognize all legal LaTeX code, only relatively simple examples. It does not associate arguments with macros, that needs to be done after parsing, with knowledge of the definitions of each macro. The main intention for this function is to process simple LaTeX code used in bibliographic references, not fully general LaTeX documents.

Verbose text is allowed in three forms: the `\verb` macro (with single character delimiters), environments whose names are listed in the `verbatim` argument, and other macros (with brace delimiters) whose names are listed in the `verb` argument.

## Value

The `parseLatex()` function returns a recursive object of class "LaTeX". Each of the entries in this object will have a "latex\_tag" attribute identifying its syntactic role.

The `deparseLatex()` function returns a single element character vector, possibly containing embedded newlines.

The `latexToUtf8()` function returns a modified version of the "LaTeX" object that was passed to it.

## Author(s)

Duncan Murdoch

## Examples

```
latex <- parseLatex("fran\\c{c}ais")
deparseLatex(latexToUtf8(latex))
```

---

parse\_Rd

*Parse an Rd File*

---

## Description

This function reads an R documentation (Rd) file and parses it, for processing by other functions.

## Usage

```
parse_Rd(file, srcfile = NULL, encoding = "unknown",
         verbose = FALSE, fragment = FALSE, warningCalls = TRUE,
         macros = file.path(R.home("share"), "Rd", "macros", "system.Rd"),
         permissive = FALSE)
## S3 method for class 'Rd'
print(x, deparse = FALSE, ...)
## S3 method for class 'Rd'
as.character(x, deparse = FALSE, ...)
```

**Arguments**

|              |                                                                                                                     |
|--------------|---------------------------------------------------------------------------------------------------------------------|
| file         | A filename or text-mode connection. At present filenames work best.                                                 |
| srcfile      | NULL, or a "srcfile" object. See the 'Details' section.                                                             |
| encoding     | Encoding to be assumed for input strings.                                                                           |
| verbose      | Logical indicating whether detailed parsing information should be printed.                                          |
| fragment     | Logical indicating whether file represents a complete Rd file, or a fragment.                                       |
| warningCalls | Logical: should parser warnings include the call?                                                                   |
| macros       | Filename or environment from which to load additional macros, or a logical value. See the Details below.            |
| permissive   | Logical indicating that unrecognized macros should be treated as text with no warning.                              |
| x            | An object of class Rd.                                                                                              |
| deparse      | If TRUE, attempt to reinstate the escape characters so that the resulting characters will parse to the same object. |
| ...          | Further arguments to be passed to or from other methods.                                                            |

**Details**

This function parses 'Rd' files according to the specification given in <https://developer.r-project.org/parseRd.pdf>.

It generates a warning for each parse error and attempts to continue parsing. In order to continue, it is generally necessary to drop some parts of the file, so such warnings should not be ignored.

Files without a marked encoding are by default assumed to be in the native encoding. An alternate default can be set using the encoding argument. All text in files is translated to the UTF-8 encoding in the parsed object.

As from R version 3.2.0, User-defined macros may be given in a separate file using '\newcommand' or '\renewcommand'. An environment may also be given: it would be produced by [loadRdMacros](#), [loadPkgRdMacros](#), or by a previous call to parse\_Rd. If a logical value is given, only the default built-in macros will be used; FALSE indicates that no "macros" attribute will be returned with the result.

The permissive argument allows text to be parsed that is not completely in Rd format. Typically it would be LaTeX code, used in an Rd fragment, e.g. in a [bibentry](#). With permissive = TRUE, this will be passed through as plain text. Since parse\_Rd doesn't know how many arguments belong in LaTeX macros, it will guess based on the presence of braces after the macro; this is not infallible.

**Value**

parse\_Rd returns an object of class "Rd". The internal format of this object is subject to change. The as.character() and print() methods defined for the class return character vectors and print them, respectively.

Unless macros = FALSE, the object will have an attribute named "macros", which is an environment containing the macros defined in file, in a format that can be used for further parse\_Rd calls in the same session. It is not guaranteed to work if saved to a file and reloaded in a different session.

|----------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| package        | typically a character string giving the name of an installed package. Can also be a file path or URL pointing to a source tarball (this feature is experimental).                                                                                                                                             |
| dir            | character string giving the path to a directory containing an installed or source package.                                                                                                                                                                                                                    |
| lib.loc        | a character vector describing the location of R library trees to search through, or NULL. Passed on to <a href="#">find.package</a> and <a href="#">Rd_db</a> .                                                                                                                                               |
| outputEncoding | character string; see <a href="#">Rd2HTML</a> .                                                                                                                                                                                                                                                               |
| stylesheet     | character string giving URL containing CSS style information.                                                                                                                                                                                                                                                 |
| hooks          | A list of functions controlling details of output. Currently the only component used is <code>pkg_href</code> , which is used to determine the output HTML file path given a package name as input.                                                                                                           |
| texmath        | character string controlling math rendering library to be used, either "katex" or "mathjax". The default is to use "katex", unless the package appears to use the <a href="#">mathjaxr</a> package in at least one of its documentation files. The support for MathJax is experimental and may not work well. |
| prism          | logical flag controlling code highlighting, as described in <a href="#">Rd2HTML</a> .                                                                                                                                                                                                                         |

|                     |                                                                                                                                                                                           |
|---------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| out                 | a filename or connection object to which to write the output. By default (NULL), the filename is inferred from <code>hooks\$pkg_href</code> , which defaults to <code>'pkg.html'</code> . |
| toc_entry           | Determines whether the entry for a help page in the table of contents is the name of the help page or its title.                                                                          |
| ...                 | additional arguments, passed on to <a href="#">Rd2HTML</a> . The <code>stages</code> argument, if specified, is passed on to <a href="#">Rd_db</a> .                                      |
| Rhtml               | logical: whether the output is intended to be a Rhtml file that can be processed using <b>knitr</b> . If TRUE, the examples section is wrapped inside a <code>rcode</code> block.         |
| mathjax_config      | character string giving path of file containing configuration instructions for MathJax. Relevant only if <code>texmath = "mathjax"</code> .                                               |
| include_description | logical flag indicating whether the output should begin with the contents of the DESCRIPTION file.                                                                                        |

### Details

The `pkg2HTML` function is intended to produce a single-page HTML reference manual for a given package, with links to other packages. The URLs of links to external packages are controlled by the provided hooks.

The handling of `\Sexpr`-s are necessarily incomplete, but can be controlled to some extent by specifying the `stages` argument. Best results are likely for installed packages.

### Value

The name of the output file (invisibly).

### Author(s)

Deepayan Sarkar

### See Also

[parse\\_Rd](#), [Rd\\_db](#), [Rd2HTML](#).

### Examples

```
pkg2HTML("tools", out = tempfile(fileext = ".html")) |> browseURL()
```

---

pskill

*Kill a Process*

---

### Description

`pskill` sends a signal to a process, usually to terminate it.

## Usage

```
pskill(pid, signal = SIGTERM)
```

```
SIGHUP  
SIGINT  
SIGQUIT  
SIGKILL  
SIGTERM  
SIGSTOP  
SIGTSTP  
SIGCHLD  
SIGUSR1  
SIGUSR2
```

## Arguments

|        |                                                                                        |
|--------|----------------------------------------------------------------------------------------|
| pid    | positive integers: one or more process IDs as returned by <a href="#">Sys.getpid</a> . |
| signal | integer, most often one of the symbolic constants.                                     |

## Details

Signals are a C99 concept, but only a small number are required to be supported (of those listed, only SIGINT and SIGTERM). They are much more widely used on POSIX operating systems (which should define all of those listed here), which also support a kill system call to send a signal to a process, most often to terminate it. Function pskill provides a wrapper: it silently ignores invalid values of its arguments, including zero or negative pids.

In normal use on a Unix-alike, Ctrl-C sends SIGINT, Ctrl-\ sends SIGQUIT and Ctrl-Z sends SIGTSTP: that and SIGSTOP suspend a process which can be resumed by SIGCONT.

The signals are small integers, but the actual numeric values are not standardized (and most do differ between OSes). The SIG\* objects contain the appropriate integer values for the current platform (or NA\_INTEGER\_ if the signal is not defined).

Only SIGINT and SIGTERM will be defined on Windows, and pskill will always use the Windows system call TerminateProcess.

## Value

A logical vector of the same length as pid, TRUE (for success) or FALSE, invisibly.

## See Also

Package **parallel** has several means to launch child processes which record the process IDs.

[psnice](#)

## Examples

```
## Not run:  
pskill(c(237, 245), SIGKILL)  
  
## End(Not run)
```

psnice

*Get or Set the Priority (Niceness) of a Process***Description**

Get or set the ‘niceness’ of the current process, or one or more other processes.

**Usage**

```
psnice(pid = Sys.getpid(), value = NA_integer_)
```

**Arguments**

|       |                                                                                                 |
|-------|-------------------------------------------------------------------------------------------------|
| pid   | positive integers: the process IDs of one or more processes: defaults to the R session process. |
| value | The niceness to be set, or NA for an enquiry.                                                   |

**Details**

POSIX operating systems have a concept of process priorities, usually from 0 to 39 (or 40) with 20 being a normal priority and (somewhat confusingly) larger numeric values denoting lower priority. To add to the confusion, there is a ‘niceness’ value, the amount by which the priority numerically exceeds 20 (which can be negative). Processes with high niceness will receive less CPU time than those with normal priority. On some OSes, processes with niceness +19 are only run when the system would otherwise be idle.

On many OSes utilities such as `top` report the priority and not the niceness. Niceness is used by the utility ‘/usr/bin/renice’: ‘/usr/bin/nice’ (and /usr/bin/renice -n) specifies an *increment* in niceness.

Only privileged users (usually super-users) can lower the niceness.

Windows has a slightly different concept of ‘priority classes’. We have mapped the idle priority to niceness 19, ‘below normal’ to 15, normal to 0, ‘above normal’ to -5 and ‘realtime’ to -10. Unlike Unix-alikes, a non-privileged user can increase the priority class on Windows (but using ‘realtime’ is inadvisable).

**Value**

An integer vector of *previous* niceness values, NA if unknown for any reason.

**See Also**

Various functions in package **parallel** create child processes whose priority may need to be changed. [pskill](#).

**Description**

Functions for performing various quality control (QC) checks on R code and documentation, notably on R packages.

**Usage**

```
checkDocFiles (package, dir, lib.loc = NULL, chkInternal = NULL)
checkDocStyle (package, dir, lib.loc = NULL)
checkReplaceFuns(package, dir, lib.loc = NULL)
checkS3methods (package, dir, lib.loc = NULL)
checkRdContents (package, dir, lib.loc = NULL, chkInternal = NULL)
```

```
langElts
nonS3methods(package)
```

**Arguments**

|                          |                                                                                                                                                                                                                                                                                 |
|--------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>package</code>     | a character string naming an installed package.                                                                                                                                                                                                                                 |
| <code>dir</code>         | a character string specifying the path to a package's root source (or <i>installed</i> in some cases) directory. This should contain the subdirectories 'R' (for R code) and 'man' with R documentation sources (in Rd format). Only used if <code>package</code> is not given. |
| <code>lib.loc</code>     | a character vector of directory names of R libraries, or NULL. The default value of NULL corresponds to all libraries currently known. The specified library trees are used to search for package.                                                                              |
| <code>chkInternal</code> | logical indicating if Rd files marked with keyword <code>internal</code> should be checked as well. If NULL (default), these are checked "specially", ignoring missing documentation of arguments.                                                                              |

**Details**

`checkDocFiles` checks, for all Rd files in a package, whether all functions shown in the usage section of the Rd file have a corresponding `\alias`, and all of their arguments are documented in the arguments section. It also reports duplicated entries in the arguments section, and 'over-documented' arguments which are given in the arguments section but not in the usage.

`checkDocStyle` investigates how (S3) methods are shown in the usages of the Rd files in a package. It reports the methods shown by their full name rather than using the Rd `\method` markup for indicating S3 methods. Earlier versions of R also reported about methods shown along with their generic, which typically caused problems for the documentation of the primary argument in the generic and its methods. With `\method` now being expanded in a way that class information is preserved, joint documentation is no longer necessarily a problem. (The corresponding information is still contained in the object returned by `checkDocStyle`.)

`checkReplaceFuns` checks whether replacement functions or S3/S4 replacement methods in the package R code have their final argument named `value`.

`checkS3methods` checks whether all S3 methods defined in the package R code have all arguments of the corresponding generic, with positional arguments of the generics in the same positions for

the method. As an exception, the first argument of a formula method *may* be called `formula` even if this is not the name used by the generic. The rules when `...` is involved are subtle: see the source code. Functions recognized as S3 generics are those with a call to `UseMethod` in their body, internal S3 generics (see [InternalMethods](#)), and S3 group generics (see [Math](#)). Possible dispatch under a different name is not taken into account. The generics are sought first in the given package, then (if given an installed package) in the package imports, and finally the namespace environment for the **base** package.

`checkRdContents()` checks Rd content, e.g., whether arguments of functions in the usage section have non empty descriptions.

`nonS3methods(package)` returns a [character](#) vector with the names of the functions in package which ‘look’ like S3 methods, but are not. Using `package = NULL` returns all known examples.

`langElts` is a character vector of names of “language elements” of R. These are implemented as “very primitive” functions (no argument list; `print()`ing as `.Primitive("name")`).

If using an installed package, the checks needing access to all R objects of the package will load the package (unless it is the **base** package), after possibly detaching an already loaded version of the package.

## Value

The functions return objects of class the same as the respective function names containing the information about problems detected. There are print methods for nicely displaying the information contained in such objects.

---

R

---

*Call Function in Inferior R Process*

---

## Description

Call a function with given arguments in a new (“inferior”) R process.

## Usage

```
R(fun, args = list(), opts = "--no-save --no-restore",
  env = character(), arch = "", drop = TRUE, timeout = 0)
```

## Arguments

|                      |                                                                                                                                                                                                                                                                                                                                                                   |
|----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>fun</code>     | a function to call in the inferior R process.                                                                                                                                                                                                                                                                                                                     |
| <code>args</code>    | a list of arguments to the function call.                                                                                                                                                                                                                                                                                                                         |
| <code>opts</code>    | a character vector of command line options to use when starting the inferior R process.                                                                                                                                                                                                                                                                           |
| <code>env</code>     | a character vector of name=value strings to set environment variables to use when starting the inferior R process.                                                                                                                                                                                                                                                |
| <code>arch</code>    | a character string giving a sub-architecture to use for the inferior R process.                                                                                                                                                                                                                                                                                   |
| <code>drop</code>    | a logical controlling what gets returned in case of “success” (when there was no error running the inferior R process and the value of the function call is not a condition object). By default, in this case only that value is returned. If <code>drop = FALSE</code> , a list with that value and status, stdout and stderr of running the inferior R process. |
| <code>timeout</code> | a timeout in seconds for the inferior R process, ignored if 0.                                                                                                                                                                                                                                                                                                    |

## Details

The given function and argument list are serialized into a tempfile. Then, an inferior R process is run via (a wrapper for) `system2()` as controlled by arguments `opts`, `env`, `arch` and `timeout`, the input of which loads the tempfile and calls the function with the argument list. It is ensured that an appropriate CRAN mirror is set.

## Value

In case of “success” (see above), the value of the function call if `drop = TRUE` (default), or a named list with the value and the status, stdout and stderr of running the inferior R process.

Otherwise, currently an error condition object inheriting from “`inferiorCallError`” with the result (status, stdout and stderr) of running the inferior R process, and in case this was successfully run but the value of the function call is a condition object, that object in the value element.

What gets returned in the non-success case may change in the future, perhaps using two different classes for the two cases of “failure” (i.e., failure in running the inferior R process or calling the function).

## Examples

```
## Compute cos(0) in an inferior R process.
## By default, only return the value of the function call.
R(cos, list(0))
## If 'drop = FALSE', we also get status, stdout and stderr.

R(cos, list(0), drop = FALSE)

## A call giving an error:
(e <- tryCatch(R(stop, list("FOOBAR")), error = identity))
## The inferior R process ran successfully:
e$status
## The function call gave an error:
e$value
```

---

Rcmd

R CMD *Interface*

---

## Description

Invoke R CMD tools from within R.

## Usage

```
Rcmd(args, ...)
```

## Arguments

|                   |                                                  |
|-------------------|--------------------------------------------------|
| <code>args</code> | a character vector of arguments to R CMD.        |
| <code>...</code>  | arguments to be passed to <code>system2</code> . |

## Details

Provides a portable convenience interface to the R CMD mechanism by invoking the corresponding system commands (using the version of R currently used) via [system2](#).

## Value

See section “Value” in [system2](#).

---

Rd2HTML

*Rd Converters*

---

## Description

These functions take the output of [parse\\_Rd\(\)](#), an Rd object, and produce a help page from it. As they are mainly intended for internal use, their interfaces are subject to change.

## Usage

```
Rd2HTML(Rd, out = "", package = "", defines = .Platform$OS.type,
        Links = NULL, Links2 = NULL,
        stages = "render", outputEncoding = "UTF-8",
        dynamic = FALSE, no_links = FALSE, fragment = FALSE,
        stylesheet = if (dynamic) "/doc/html/R.css" else "R.css",
        texmath = getOption("help.htmlmath"),
        concordance = FALSE,
        standalone = TRUE,
        hooks = list(),
        toc = isTRUE(getOption("help.htmltoc")),
        Rhtml = FALSE,
        ...)
```

```
Rd2txt(Rd, out = "", package = "", defines = .Platform$OS.type,
        stages = "render", outputEncoding = "",
        fragment = FALSE, options, ...)
```

```
Rd2latex(Rd, out = "", defines = .Platform$OS.type,
        stages = "render", outputEncoding = "UTF-8",
        fragment = FALSE, ..., writeEncoding = outputEncoding != "UTF-8",
        concordance = FALSE)
```

```
Rd2ex(Rd, out = "", defines = .Platform$OS.type,
        stages = "render", outputEncoding = "UTF-8",
        commentDontrun = TRUE, commentDonttest = FALSE, ...)
```

## Arguments

|         |                                                                                                                                      |
|---------|--------------------------------------------------------------------------------------------------------------------------------------|
| Rd      | a filename or Rd object to use as input.                                                                                             |
| out     | a filename or connection object to which to write the output. The default out = "" is equivalent to out = <a href="#">stdout()</a> . |
| package | the package to list in the output.                                                                                                   |

|                 |                                                                                                                                                                                                                                                                                                                                                                                                   |
|-----------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| defines         | string(s) to use in <code>#ifdef</code> tests.                                                                                                                                                                                                                                                                                                                                                    |
| stages          | at which stage ("build", "install", or "render") should <code>\Sexpr</code> macros be executed? See the notes below.                                                                                                                                                                                                                                                                              |
| outputEncoding  | see the 'Encodings' section below.                                                                                                                                                                                                                                                                                                                                                                |
| dynamic         | logical: set links for render-time resolution by dynamic help system.                                                                                                                                                                                                                                                                                                                             |
| no_links        | logical: suppress hyperlinks to other help topics. Used by R CMD <code>Rdconv</code> .                                                                                                                                                                                                                                                                                                            |
| fragment        | logical: should fragments of Rd files be accepted? See the notes below.                                                                                                                                                                                                                                                                                                                           |
| stylesheet      | character: a URL for a stylesheet to be used in the header of the HTML output page.                                                                                                                                                                                                                                                                                                               |
| texmath         | character: controls how mathematics in <code>\eqn</code> and <code>\deqn</code> commands are typeset in HTML output. Useful values are "katex" (default) and "mathjax" to use <b>KaTeX</b> or <b>MathJax</b> respectively, otherwise basic substitutions are used. May be ignored under certain circumstances, e.g., if the help page already uses macros from the <code>mathjaxr</code> package. |
| concordance     | Whether concordance data should be embedded in the output file and attached to the return value.                                                                                                                                                                                                                                                                                                  |
| standalone      | logical: whether the output is intended to be a standalone HTML file. If FALSE, the header and footer are omitted, so that the output can be combined with other fragments.                                                                                                                                                                                                                       |
| hooks           | a list of functions controlling details of output. Currently the only component used is <code>pkg_href</code> , which is used by <code>pkg2HTML</code> to determine the output HTML file path given a package name as input.                                                                                                                                                                      |
| toc             | logical: whether the HTML output should include a table of contents. Ignored unless <code>standalone = TRUE</code> .                                                                                                                                                                                                                                                                              |
| Rhtml           | logical: whether the output is intended to be a Rhtml file that can be processed using <b>knitr</b> . If TRUE, the examples section is wrapped inside a <code>rcode</code> block.                                                                                                                                                                                                                 |
| Links, Links2   | NULL or a named (by topics) character vector of links, as returned by <code>findHTMLlinks</code> .                                                                                                                                                                                                                                                                                                |
| options         | an optional named list of options to pass to <code>Rd2txt_options</code> .                                                                                                                                                                                                                                                                                                                        |
| ...             | additional parameters to pass to <code>parse_Rd</code> when Rd is a filename.                                                                                                                                                                                                                                                                                                                     |
| writeEncoding   | logical: should an <code>\inputencoding</code> line be written for non-ASCII encodings? $\LaTeX$ release 2018-04-01 and later default to UTF-8; the declaration is obsolete in that case.                                                                                                                                                                                                         |
| commentDontrun  | logical: should <code>\dontrun</code> sections be commented out?                                                                                                                                                                                                                                                                                                                                  |
| commentDonttest | logical: should <code>\donttest</code> sections be commented out?                                                                                                                                                                                                                                                                                                                                 |

## Details

These functions convert help documents: `Rd2HTML` produces HTML, `Rd2txt` produces plain text, `Rd2latex` produces LaTeX. `Rd2ex` extracts the examples in the format used by `example` and R utilities.

Each of the functions accepts a filename for an Rd file, and will use `parse_Rd` to parse it before applying the conversions or checks.

The difference between arguments `Link` and `Link2` is that links are looked in them in turn, so lazy-evaluation can be used to only do a second-level search for links if required.

Before R 3.6.0, the default for `Rd2latex` was `outputEncoding = "ASCII"`, including using the second option of `\enc` markup, because  $\text{\LaTeX}$  versions did not provide enough coverage of UTF-8 glyphs for a long time.

`Rd2txt` will format text paragraphs to a width determined by `width`, with appropriate margins. The default is to be close to the rendering in versions of R < 2.10.0.

`Rd2txt` will use directional quotes (see [sQuote](#)) if option `"useFancyQuotes"` is true (usually the default, see [sQuote](#)) and the current encoding is UTF-8.

Various aspects of formatting by `Rd2txt` are controlled by the `options` argument, documented with the [Rd2txt\\_options](#) function. Changes made using options are temporary, those made with [Rd2txt\\_options](#) are persistent.

When `fragment = TRUE`, the Rd file will be rendered with no processing of `\Sexpr` elements or conditional defines using `#ifdef` or `#ifndef`. Normally a fragment represents text within a section, but if the first element of the fragment is a section macro, the whole fragment will be rendered as a series of sections, without the usual sorting.

## Value

These functions are executed mainly for the side effect of writing the converted help page. Their value is the name of the output file (invisibly). For `Rd2latex`, the output name is given an attribute `"latexEncoding"` giving the encoding of the file in a form suitable for use with the LaTeX `'inputenc'` package. For `Rd2HTML` with `standalone = FALSE`, an attribute `"info"` gives supplementary information such as the contents of the name and title fields. This is currently experimental, and the details are subject to change.

For `Rd2HTML` and `Rd2latex` with `concordance = TRUE`, a `"concordance"` attribute is added, containing an [Rconcordance](#) object.

## Encodings

Rd files are normally intended to be rendered on a wide variety of systems, so care must be taken in the encoding of non-ASCII characters. In general, any such encoding should be declared using the `'encoding'` section for there to be any hope of correct rendering.

For output, the `outputEncoding` argument will be used: `outputEncoding = ""` will choose the native encoding for the current system.

If the text cannot be converted to the `outputEncoding`, byte substitution will be used (see [iconv](#)): `Rd2latex` and `Rd2ex` give a warning.

## Note

The `\Sexpr` macro includes R code that will be executed at one of three times: *build* time (when a package's source code is built into a tarball), *install* time (when the package is installed or built into a binary package), and *render* time (when the man page is converted to a readable format).

For example, this man page was:

1. built on 2025-07-10 at 10:33:13,
2. installed on 2025-07-10 at 10:33:13, and
3. rendered on 2025-07-10 at 10:37:56.

Rd2txt\_options

*Set Formatting Options for Text Help*

---

## Description

This function sets various options for displaying text help.

## Usage

```
Rd2txt_options(...)
```

## Arguments

... A list containing named options, or options passed as individual named arguments. See below for currently defined ones.

## Details

This function persistently sets various formatting options for the [Rd2txt](#) function which is used in displaying text format help. Currently defined options are:

**width** (default 80): The width of the output page.

**minIndent** (default 10): The minimum indent to use in a list.

**extraIndent** (default 4): The extra indent to use in each level of nested lists.

**sectionIndent** (default 5): The indent level for a section.

**sectionExtra** (default 2): The extra indentation for each nested section level.

**itemBullet** (default " \* ", with the asterisk replaced by a Unicode bullet in UTF-8 and most Windows locales): The symbol to use as a bullet in itemized lists.

**enumFormat** : A function to format item numbers in enumerated lists.

**showURLs** (default FALSE): Whether to show URLs when expanding \href tags.

**code\_quote** (default TRUE): Whether to render \code and similar with single quotes.

**underline\_titles** (default TRUE): Whether to render section titles with underlines (via backspacing).

**Value**

If called with no arguments, returns all option settings in a list. Otherwise, it changes the named settings and invisibly returns their previous values.

**Author(s)**

Duncan Murdoch

**See Also**

[Rd2txt](#)

**Examples**

```
saveOpts <- Rd2txt_options()
saveOpts
Rd2txt_options(minIndent = 4)
Rd2txt_options()[["minIndent"]]
Rd2txt_options(saveOpts)
stopifnot(identical(Rd2txt_options(), saveOpts))
```

---

Rdiff

*Difference R Output Files*

---

**Description**

Given two R output files, compute differences ignoring headers, footers and some other differences.

**Usage**

```
Rdiff(from, to, useDiff = FALSE, forEx = FALSE,
      nullPointers = TRUE, Log = FALSE)
```

**Arguments**

|              |                                                                                                                                |
|--------------|--------------------------------------------------------------------------------------------------------------------------------|
| from, to     | filepaths to be compared                                                                                                       |
| useDiff      | should diff be used to compare results? Overridden to false if the command is not available.                                   |
| forEx        | logical: extra pruning for ‘-Ex.Rout’ files to exclude headers and footers of examples, code and results for “--timings”, etc. |
| nullPointers | logical: should the displayed addresses of pointers be set to 0x00000000 before comparison?                                    |
| Log          | logical: should the returned value include a log of differences found?                                                         |

## Details

The R startup banner and any timing information from R CMD BATCH are removed from both files, together with lines about loading packages. UTF-8 fancy quotes (see [sQuote](#)) and on Windows, Windows' so-called 'smart quotes', are mapped to a simple quote. Addresses of environments, compiled bytecode and other exotic types expressed as hex addresses (e.g., '<environment: 0x12345678>') are mapped to 0x00000000. The files are then compared line-by-line. If there are the same number of lines and useDiff is false, a simple diff -b -like display of differences is printed (which ignores trailing spaces and differences in numbers of consecutive spaces), otherwise diff -bw is called on the edited files. (This tries to ignore all differences in whitespace: note that flag '-w' is not required by POSIX but is supported by GNU, Solaris and FreeBSD versions – macOS uses an old GNU version.)

There is limited support for comparing PDF files produced by pdf(compress = FALSE), mainly for use in make check – this requires a diff command and useDiff = TRUE.

Mainly for use in examples and tests, text from marker '> ## IGNORE\_RDIFF\_BEGIN' up to (but not including) '> ## IGNORE\_RDIFF\_END' is ignored. In examples, since R 4.4.0, the built-in Rd macro \dontdiff{} can be used instead.

## Value

If Log is true, a list with components status (see below) and out, a character vector of descriptions of differences, possibly of zero length.

Otherwise, a status indicator (invisibly), 0L if and only if no differences were found.

## See Also

The shell script run as R CMD Rdiff, which uses useDiff = TRUE.

---

|         |                                     |
|---------|-------------------------------------|
| Rdindex | <i>Generate Index from Rd Files</i> |
|---------|-------------------------------------|

---

## Description

Print a 2-column index table with names and titles from given R documentation files to a given output file or connection. The titles are nicely formatted between two column positions (typically 25 and 72, respectively).

## Usage

```
Rdindex(RdFiles, outFile = "", type = NULL,
        width = 0.9 * getOption("width"), indent = NULL)
```

## Arguments

|         |                                                                                                                                                                                         |
|---------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| RdFiles | a character vector specifying the Rd files to be used for creating the index, either by giving the paths to the files, or the path to a single directory with the sources of a package. |
| outFile | a connection, or a character string naming the output file to print to. "" (the default) indicates output to the console.                                                               |

|        |                                                                                                                                                                                                                                                                                               |
|--------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| type   | a character string giving the documentation type of the Rd files to be included in the index, or NULL (the default). The type of an Rd file is typically specified via the <code>\docType</code> tag; if type is "data", Rd files whose <i>only</i> keyword is datasets are included as well. |
| width  | a positive integer giving the target column for wrapping lines in the output.                                                                                                                                                                                                                 |
| indent | a positive integer specifying the indentation of the second column. Must not be greater than width/2, and defaults to width/3.                                                                                                                                                                |

## Details

If a name is not a valid alias, the first alias (or the empty string if there is none) is used instead.

---

|              |                                  |
|--------------|----------------------------------|
| RdTextFilter | <i>Select Text in an Rd File</i> |
|--------------|----------------------------------|

---

## Description

This function blanks out all non-text in an Rd file, for spell checking or other uses.

## Usage

```
RdTextFilter(ifile, encoding = "unknown", keepSpacing = TRUE,
             drop = character(), keep = character(),
             macros = file.path(R.home("share"), "Rd", "macros", "system.Rd"))
```

## Arguments

|             |                                                                                                        |
|-------------|--------------------------------------------------------------------------------------------------------|
| ifile       | An input file specified as a filename or connection, or an "Rd" object from <a href="#">parse_Rd</a> . |
| encoding    | An encoding name to pass to <a href="#">parse_Rd</a> .                                                 |
| keepSpacing | Whether to try to leave the text in the same lines and columns as in the original file.                |
| drop        | Additional sections of the Rd to drop.                                                                 |
| keep        | Sections of the Rd file to keep.                                                                       |
| macros      | Macro definitions to assume when parsing. See <a href="#">parse_Rd</a> .                               |

## Details

This function parses the Rd file, then walks through it, element by element. Items with tag "TEXT" are kept in the same position as they appeared in the original file, while other parts of the file are replaced with blanks, so a spell checker such as [aspell](#) can check only the text and report the position in the original file. (If keepSpacing is FALSE, blank filling will not occur, and text will not be output in its original location.)

By default, the tags `\S3method`, `\S4method`, `\command`, `\docType`, `\email`, `\encoding`, `\file`, `\keyword`, `\link`, `\linkS4class`, `\method`, `\pkg`, and `\var` are skipped. Additional tags can be skipped by listing them in the drop argument; listing tags in the keep argument will stop them from being skipped. It is also possible to keep any of the `c("RCODE", "COMMENT", "VERB")` tags, which correspond to R-like code, comments, and verbatim text respectively, or to drop "TEXT".

**Value**

A character vector which if written to a file, one element per line, would duplicate the text elements of the original Rd file.

**Note**

The filter attempts to merge text elements into single words when markup in the Rd file is used to highlight just the start of a word.

**Author(s)**

Duncan Murdoch

**See Also**

[aspell](#), for which this is an acceptable filter.

---

|         |                     |
|---------|---------------------|
| Rdutils | <i>Rd Utilities</i> |
|---------|---------------------|

---

**Description**

Utilities for computing on the information in Rd objects.

**Usage**

```
Rd_db(package, dir, lib.loc = NULL, stages = "build")
```

**Arguments**

|         |                                                                                                                                                                                                         |
|---------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| package | a character string naming an installed package.                                                                                                                                                         |
| dir     | a character string specifying the path to a package's root source directory. This should contain the subdirectory 'man' with R documentation sources (in Rd format). Only used if package is not given. |
| lib.loc | a character vector of directory names of R libraries, or NULL. The default value of NULL corresponds to all libraries currently known. The specified library trees are used to search for package.      |
| stages  | if dir is specified and the database is being built from source, which stages of \Sexpr processing should be processed?                                                                                 |

**Details**

Rd\_db builds a simple database of all Rd objects in a package, as a list of the results of running [parse\\_Rd](#) on the Rd source files in the package and processing platform conditionals and some \Sexpr macros.

**See Also**

[parse\\_Rd](#)

## Examples

```
## Build the Rd db for the (installed) base package.
db <- Rd_db("base")

## Keyword metadata per Rd object.
keywords <- lapply(db, tools::.Rd_get_metadata, "keyword")
## Tabulate the keyword entries.
kw_table <- sort(table(unlist(keywords)))
## The 5 most frequent ones:
rev(kw_table)[1 : 5]
## The "most informative" ones:
kw_table[kw_table == 1]

## Concept metadata per Rd file.
concepts <- lapply(db, tools::.Rd_get_metadata, "concept")
## How many files already have \concept metadata?
sum(sapply(concepts, length) > 0)
## How many concept entries altogether?
length(unlist(concepts))
```

---

read.00Index

*Read 00Index-style Files*

---

## Description

Read item/description information from ‘00Index’-like files. Such files are description lists rendered in tabular form, and currently used for the ‘INDEX’ and ‘demo/00Index’ files of add-on packages.

## Usage

```
read.00Index(file)
```

## Arguments

|      |                                                                                                                                                                                                                                                                                                                        |
|------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| file | the name of a file to read data values from. If the specified file is "", then input is taken from the keyboard (in this case input can be terminated by a blank line). Alternatively, file can be a <a href="#">connection</a> , which will be opened if necessary, and if so closed at the end of the function call. |
|------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

## Value

A character matrix with 2 columns named "Item" and "Description" which hold the items and descriptions.

## See Also

[formatDL](#) for the inverse operation of creating a 00Index-style file from items and their descriptions.

---

sha256sum*Compute SHA-256 Checksums*

---

## Description

Compute the 32-byte SHA-256 hashes of one or more files, or a raw vector of bytes.

## Usage

```
sha256sum(files, bytes)
```

## Arguments

|                    |                                                                                       |
|--------------------|---------------------------------------------------------------------------------------|
| <code>files</code> | character. The paths of file(s) whose contents are to be hashed.                      |
| <code>bytes</code> | <a href="#">raw</a> . Bytes to be hashed. NB: bytes and files are mutually exclusive. |

## Details

A SHA-256 ‘hash’ or ‘checksum’ or ‘message digest’ is a 256-bit summary of the file contents represented by 64 hexadecimal digits.

On Windows all files are read in binary mode (as the sha256sum utilities there do); on other OSes the files are read in the default mode (almost always text mode where there is more than one).

## Value

If used with files, a character vector of the same length as files, with names equal to files (possibly expanded). The elements will be NA for non-existent or unreadable files, otherwise a 64-character string of hexadecimal digits.

For bytes the result is a single 64-character string.

## Source

The underlying C code was written by Ulrich Drepper, extracted from the public domain version ‘SHA-crypt.txt’ version 0.6 (2016-8-31).

## See Also

[md5sum](#)

## Examples

```
as.vector sha256sum(dir(R.home(), pattern = "^COPY", full.names = TRUE))
sha256sum(bytes=raw())
sha256sum(bytes=charToRaw("abc"))
```

showNonASCII

*Pick Out Non-ASCII Characters*

---

**Description**

This function prints elements of a character vector which contain non-ASCII bytes, printing such bytes as a escape like '<fc>'.

**Usage**

```
showNonASCII(x)
```

```
showNonASCIIfile(file)
```

**Arguments**

|      |                     |
|------|---------------------|
| x    | a character vector. |
| file | path to a file.     |

**Details**

This was originally written to help detect non-portable text in files in packages.

It prints all elements of x which contain non-ASCII characters, preceded by the element number and with non-ASCII bytes highlighted *via* `iconv`(sub = "byte").

However, this rendering depends on `iconv`(to = "ASCII") failing to convert, and macOS 14 no longer does so reliably so for example permille ('`\u2030`') is rendered as o/oo.

**Value**

The elements of x containing non-ASCII characters will be returned invisibly.

**Examples**

```
out <- c(
  "fran\xE7ais: test of showNonASCII():",
  "\\details{",
  "  This is a good line",
  "  This has an \xfcmlaut in it.",
  "  OK again.",
  "}")
f <- tempfile()
cat(out, file = f, sep = "\n")

showNonASCIIfile(f)
unlink(f)
```

---

|                  |                                           |
|------------------|-------------------------------------------|
| startDynamicHelp | <i>Start the Dynamic HTML Help System</i> |
|------------------|-------------------------------------------|

---

## Description

This function starts the internal help server, so that HTML help pages are rendered when requested.

## Usage

```
startDynamicHelp(start = TRUE)
```

## Arguments

|       |                                                                                                                      |
|-------|----------------------------------------------------------------------------------------------------------------------|
| start | logical: whether to start or shut down the dynamic help system. If NA, the server is started if not already running. |
|-------|----------------------------------------------------------------------------------------------------------------------|

## Details

This function starts the internal HTTP server, which runs on the loopback interface ('127.0.0.1'). If `options("help.ports")` is set to a vector of non-zero integer values, `startDynamicHelp` will try those ports in order; otherwise, it tries up to 10 random ports to find one not in use. It can be disabled by setting the environment variable `R_DISABLE_HTTPD` to a non-empty value or `options("help.ports")` to `0`.

`startDynamicHelp` is called by functions that need to use the server, so would rarely be called directly by a user.

Note that `options(help_type = "html")` must be set to actually make use of HTML help, although it might be the default for an R installation.

If the server cannot be started or is disabled, [help.start](#) will be unavailable and requests for HTML help will give text help (with a warning).

The browser in use does need to be able to connect to the loopback interface: occasionally it is set to use a proxy for HTTP on all interfaces, which will not work – the solution is to add an exception for '127.0.0.1'.

## Value

The chosen port number is returned invisibly (which will be `0` if the server has been stopped).

## See Also

[help.start](#) and `help(help_type = "html")` will attempt to start the HTTP server if required. [Rd2HTML](#) is used to render the package help pages.

---

`SweaveTeXFilter`*Strip R Code out of Sweave File*

---

**Description**

This function blanks out code chunks and Noweb markup in an Sweave input file, for spell checking or other uses.

**Usage**

```
SweaveTeXFilter(ifile, encoding = "unknown")
```

**Arguments**

|                       |                                                      |
|-----------------------|------------------------------------------------------|
| <code>ifile</code>    | Input file or connection.                            |
| <code>encoding</code> | Text encoding to pass to <a href="#">readLines</a> . |

**Details**

This function blanks out all Noweb markup and code chunks from an Sweave input file, leaving behind the LaTeX source, so that a LaTeX-aware spelling checker can check it and report errors in their original locations.

**Value**

A character vector which if written to a file, one element per line, would duplicate the text elements of the original Sweave input file.

**Author(s)**

Duncan Murdoch

**See Also**

[aspell](#), for which this is used with `filter = "Sweave"`.

---

`testInstalledPackage`*Test Installed Packages*

---

**Description**

These functions allow an installed package to be tested, or all base and recommended packages.

**Usage**

```
testInstalledPackage(pkg, lib.loc = NULL, outDir = ".",
                     types = c("examples", "tests", "vignettes"),
                     srcdir = NULL, Ropts = "", ...)

testInstalledPackages(outDir = ".", errorsAreFatal = TRUE,
                      scope = c("both", "base", "recommended"),
                      types = c("examples", "tests", "vignettes"),
                      srcdir = NULL, Ropts = "", ...)

testInstalledBasic(scope = c("basic", "devel", "both", "internet", "all"),
                   outDir = file.path(R.home(), "tests"),
                   testSrcdir = getTestSrcdir(outDir))

standard_package_names()
```

**Arguments**

|                             |                                                                                                                                                                       |
|-----------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>pkg</code>            | name of an installed package.                                                                                                                                         |
| <code>lib.loc</code>        | library path(s) in which to look for the package. See <a href="#">library</a> .                                                                                       |
| <code>outDir</code>         | the directory into which to write the output files: this should already exist. The default, "." is the current working directory. Often a subdirectory is preferable. |
| <code>types</code>          | type(s) of tests to be done.                                                                                                                                          |
| <code>srcdir</code>         | Optional directory to look for .save files.                                                                                                                           |
| <code>Ropts</code>          | Additional options such as '-d valgrind' to be passed to R CMD BATCH when running examples or tests.                                                                  |
| <code>errorsAreFatal</code> | logical: should testing terminate at the first error?                                                                                                                 |
| <code>scope</code>          | a string indicating which set(s) should be tested. "both" includes "basic" and "devel"; "all" adds "internet". Can be abbreviated.                                    |
| <code>...</code>            | additional arguments use when preparing the files to be run, e.g. <code>commentDontrun</code> and <code>commentDonttest</code> .                                      |
| <code>testSrcdir</code>     | optional directory where the test R scripts are found.                                                                                                                |

**Details**

The `testInstalledPackage{s}()` tests depend on having the package example files installed (which is the default).

If package-specific tests are found in a 'tests' directory they can be tested: these are not installed by default, but will be if `R CMD INSTALL --install-tests` was used. Finally, the R code in any vignettes can be extracted and tested.

The package-specific tests are run in a '*pkg*-tests' subdirectory of '`outDir`', and leave their output there.

`testInstalledBasic` runs the basic tests, if installed or inside `testSrcdir`. This should be run with `LC_COLLATE` set to 'C': the function tries to set this but it may not work on all OSes. For non-English locales it may be desirable to set environment variables `LANGUAGE` to 'en' and `LC_TIME` to 'C' to reduce the number of differences from reference results.

Except on Windows, if the environment variable `TEST_MC_CORES` is set to an integer greater than one, `testInstalledPackages` will run the package tests in parallel using its value as the maximum number of parallel processes.

The package-specific tests for the base and recommended packages are an optional part of the install, where on unix-alikes, i.e., not on Windows, make install-tests is provided to do so (as well as the basic tests).

On Windows, currently testing requires a Unix-like diff for a full report if more than simple differences are found.

## Value

Invisibly 0L for success, 1L for failure.

standard\_package\_names() returns a **list** with components named

base                    a character vector with the ‘base’ package names.

recommended        a character vector with the ‘Recommended’ package names in historical order.

## Examples

```
str(stPkgs <- standard_package_names())

## consistency of packageDescription and standard_package_names :
(pNms <- unlist(stPkgs, FALSE))
(prio <- sapply(as.vector(pNms), packageDescription, fields = "Priority"))
stopifnot(identical(unname(prio),
                    sub("[0-9]+$", '', names(pNms))))
```

---

texi2dvi

*Compile LaTeX Files*

---

## Description

Run latex/pdflatex, makeindex and bibtex until all cross-references are resolved to create a DVI or a PDF file.

## Usage

```
texi2dvi(file, pdf = FALSE, clean = FALSE, quiet = TRUE,
         texi2dvi = getOption("texi2dvi"),
         texinputs = NULL, index = TRUE)
```

```
texi2pdf(file, clean = FALSE, quiet = TRUE,
         texi2dvi = getOption("texi2dvi"),
         texinputs = NULL, index = TRUE)
```

## Arguments

file                    character string. Name of the LaTeX source file.

pdf                    logical. If TRUE, a PDF file is produced instead of the default DVI file (texi2dvi command line option ‘--pdf’).

clean                   logical. If TRUE, all auxiliary files created during the conversion are removed.

quiet                   logical. No output unless an error occurs.

|           |                                                                                                                                                                                                                                                                                                                                    |
|-----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| texi2dvi  | character string (or NULL). Script or program used to compile a TeX file to DVI or PDF. The default (selected by "" or "texi2dvi" or NULL) is to look for a program or script named texi2dvi on the path and otherwise emulate the script with system2 calls (which can be selected by the value "emulation"). See also 'Details'. |
| texinputs | NULL or a character vector of paths to prepend to the LaTeX and BibTeX input search paths.                                                                                                                                                                                                                                         |
| index     | logical: should indices be prepared?                                                                                                                                                                                                                                                                                               |

## Details

texi2pdf is a wrapper for the common case of texi2dvi(pdf = TRUE).

Despite the name, this is used in R to compile L<sup>A</sup>T<sub>E</sub>X files, specifically those generated from vignettes and by the [Rd2pdf](#) script (used for package reference manuals). It ensures that the '[R\\_HOME](#)/share/texmf' directory is in the TEXINPUTS path, so R style files such as 'Sweave.sty' and 'Rd.sty' will be found. The TeX search path used is first the elements of argument texinputs, then the existing TEXINPUTS setting (or the current directory if unset), then '[R\\_HOME](#)/share/texmf' and finally the system paths. Analogous changes are made to BIBINPUTS and BSTINPUTS settings.

The default option for texi2dvi is set from environment variable R\_TEXI2DVICMD, and the default for that is set from environment variable TEXI2DVI or if that is unset, from a value chosen when R is configured.

A shell script texi2dvi is part of GNU Texinfo. Several issues have been seen with released versions, so if yours does not work correctly try R\_TEXI2DVICMD=emulation.

Occasionally indices contain special characters which cause indexing to fail (particularly when using the 'hyperref' LaTeX package) even on valid input. The argument index = FALSE is provided to allow package manuals to be made when this happens: it uses emulation.

## Value

Invisible NULL. Used for the side effect of creating a DVI or PDF file in the current working directory (and maybe other files, especially if clean = FALSE).

## Note

There are various versions of the texi2dvi script on Unix-alikes and quite a number of bugs have been seen, some of which this R wrapper works around.

One that was present with texi2dvi version 4.8 (as supplied by macOS) is that it will not work correctly for paths which contain spaces, nor if the absolute path to a file would contain spaces.

The three possible approaches all have their quirks. For example the Unix-alike texi2dvi script removes ancillary files that already exist but the other two approaches do not (and may get confused by such files).

Option '--max-iterations=20' is used to avoid infinite retries.

The emulation mode supports quiet = TRUE from R 3.2.3 only. Currently clean = TRUE only cleans up in this mode if the conversion was successful—this gives users a chance to examine log files in the event of error.

All the approaches should respect the values of environment variables L<sup>A</sup>T<sub>E</sub>X, PDFL<sup>A</sup>T<sub>E</sub>X, MAKEINDEX and BIBTEX for the full paths to the corresponding commands.

**Author(s)**

Originally Achim Zeileis but largely rewritten by R-core.

---

toHTML

*Display an Object in HTML*

---

**Description**

This generic function generates a complete HTML page from an object.

**Usage**

```
toHTML(x, ...)
## S3 method for class 'packageIQR'
toHTML(x, ...)
## S3 method for class 'news_db'
toHTML(x, ...)
```

**Arguments**

|     |                                                                                                                    |
|-----|--------------------------------------------------------------------------------------------------------------------|
| x   | An object to display.                                                                                              |
| ... | Optional parameters for methods; the "packageIQR" and "news_db" methods pass these to <a href="#">HTMLheader</a> . |

**Value**

A character vector to display the object x. The "packageIQR" method is designed to display lists in the R help system.

**See Also**

[HTMLheader](#)

**Examples**

```
cat(toHTML(demo(package = "base")), sep = "\n")
```

---

tools-deprecated

*Deprecated Objects in Package **tools***

---

**Description**

(Currently none)

The functions or variables listed here are provided for compatibility with older versions of R only, and may be defunct as soon as of the next release.

**See Also**

[Deprecated](#), [Defunct](#)

---

toRd

*Generic Function to Convert Object to a Fragment of Rd Code*

---

### Description

Methods for this function render their associated classes as a fragment of Rd code, which can then be rendered into text, HTML, or LaTeX.

### Usage

```
toRd(obj, ...)
## S3 method for class 'bibentry'
toRd(obj, style = NULL, ...)
```

### Arguments

|       |                                                                       |
|-------|-----------------------------------------------------------------------|
| obj   | The object to be rendered.                                            |
| style | The style to be used in converting a <a href="#">bibentry</a> object. |
| ...   | Additional arguments used by methods.                                 |

### Details

See [bibstyle](#) for a discussion of styles. The default style = NULL value gives the default style.

### Value

Returns a character vector containing a fragment of Rd code that could be parsed and rendered. The default method converts obj to mode character, then escapes any Rd markup within it. The bibentry method converts an object of that class to markup appropriate for use in a bibliography.

---

toTitleCase

*Convert Titles to Title Case*

---

### Description

Convert a character vector to title case for English, especially package titles.

### Usage

```
toTitleCase(text)
```

### Arguments

|      |                     |
|------|---------------------|
| text | a character vector. |
|------|---------------------|

## Details

This is intended for English text only.

No definition of ‘title case’ is universally accepted: all agree that ‘principal’ words are capitalized and common words like ‘for’ are not, but not which words fall into each category.

Generally words in all capitals are left alone: this implementation knows about conventional mixed-case words such as ‘LaTeX’ and ‘OpenBUGS’ and a few technical terms which are not usually capitalized such as ‘jar’ and ‘xls’. However, unknown technical terms will be capitalized unless they are single words enclosed in single quotes: names of packages and libraries should be quoted in titles.

## Value

A character vector of the same length as text, without names.

## Examples

```
toTitleCase("bayesian network modeling and analysis")
toTitleCase("ensemble tool for predictions from species distribution models")
## Treatment after "-":
toTitleCase("small- and large-scale analysis") # lowercase "and"

toTitleCase("a small fox is jumping") # "a Small Fox is .." (the 'a' may change)% i.e. BUG
toTitleCase("is a small fox jumping?") # "Is a Small Fox .." (fine)
## After ":", start a new sentence
toTitleCase("a pangram: the quick brown fox jumps over the lazy dog")
toTitleCase("asking -- 'is a small fox jumping?') # ".. -- Is a Small ..." (fine)
```

undoc

*Find Undocumented Objects*

## Description

Finds the objects in a package which are undocumented, in the sense that they are visible to the user (or data objects or S4 classes provided by the package), but no documentation entry exists.

## Usage

```
undoc(package, dir, lib.loc = NULL)
```

## Arguments

|         |                                                                                                                                                                                                                                                                    |
|---------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| package | a character string naming an installed package.                                                                                                                                                                                                                    |
| dir     | a character string specifying the path to a package’s root source directory. This must contain the subdirectory ‘man’ with R documentation sources (in Rd format), and at least one of the ‘R’ or ‘data’ subdirectories with R code or data objects, respectively. |
| lib.loc | a character vector of directory names of R libraries, or NULL. The default value of NULL corresponds to all libraries currently known. The specified library trees are used to search for package.                                                                 |

## Details

This function is useful for package maintainers mostly. In principle, *all* user-level R objects should be documented.

The **base** package is special as it contains the primitives and these do not have definitions available at code level. We provide equivalent closures in environments `.ArgsEnv` and `.GenericArgsEnv` in the **base** package that are used for various purposes: `undoc("base")` checks that all the primitives that are not language constructs are prototyped in those environments and no others are.

## Value

An object of class "undoc" which is a list of character vectors containing the names of the undocumented objects split according to documentation type.

There is a `print` method for nicely displaying the information contained in such objects.

## See Also

[codoc](#), [QC](#)

## Examples

```
undoc("tools")           # Undocumented objects in 'tools'
```

---

|                 |                                       |
|-----------------|---------------------------------------|
| update_PACKAGES | <i>Update Existing PACKAGES Files</i> |
|-----------------|---------------------------------------|

---

## Description

Update an existing repository by reading the PACKAGES file, retaining entries which are still valid, removing entries which are no longer valid, and only processing built package tarballs which do not match existing entries.

`update_PACKAGES` can be much faster than [write\\_PACKAGES](#) for small-moderate changes to large repository indexes, particularly in non-strict mode (see Details).

## Usage

```
update_PACKAGES(dir = ".", fields = NULL, type = c("source",
  "mac.binary", "win.binary"), verbose.level = as.integer(dryrun),
  latestOnly = TRUE, addFiles = FALSE, rds_compress = "xz",
  strict = TRUE, dryrun = FALSE)
```

## Arguments

|                            |                                                                                                                                                                                                      |
|----------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>dir</code>           | see <a href="#">write_PACKAGES</a> .                                                                                                                                                                 |
| <code>fields</code>        | see <a href="#">write_PACKAGES</a> .                                                                                                                                                                 |
| <code>type</code>          | see <a href="#">write_PACKAGES</a> .                                                                                                                                                                 |
| <code>verbose.level</code> | one of {0, 1, 2}, the level of informative messages displayed throughout the process. Defaults to 0 if <code>dryrun</code> is FALSE (the default) and 1 otherwise. See Details for more information. |
| <code>latestOnly</code>    | see <a href="#">write_PACKAGES</a> .                                                                                                                                                                 |

|              |                                                                                                               |
|--------------|---------------------------------------------------------------------------------------------------------------|
| addFiles     | see <a href="#">write_PACKAGES</a> .                                                                          |
| rds_compress | see <a href="#">write_PACKAGES</a> .                                                                          |
| strict       | logical. Should “strict mode” be used when checking existing PACKAGES entries. See Details. Defaults to TRUE. |
| dryrun       | logical. Should the updates to existing PACKAGES files be computed but NOT applied. Defaults to FALSE.        |

## Details

Throughout this section, *package tarball* is defined to mean any archive file in *dir* whose name can be interpreted as ‘*package\_version.ext*’ – with *ext* the appropriate extension for built packages of type *type* – (or that is pointed to by the *File* field of an existing PACKAGES entry). *Novel package tarballs* are those which do not match an existing PACKAGES file entry.

update\_PACKAGES calls directly down to [write\\_PACKAGES](#) with a warning (and thus all package tarballs will be processed), if any of the following conditions hold:

- type is “win.binary” and strict is TRUE (no MD5 checksums are included in win.binary PACKAGES files)
- No PACKAGES file exists under *dir*
- A PACKAGES file exists under *dir* but is empty
- fields is not NULL and one or more specified fields are not present in the existing PACKAGES file

update\_PACKAGES avoids (re)processing package tarballs in cases where a PACKAGES file entry already exists and appears to remain valid. The logic for detecting still-valid entries is as follows:

Any package tarball which was last modified more recently than the existing PACKAGES file is considered novel; existing PACKAGES entries appearing to correspond to such tarballs are *always* considered stale and replaced by newly generated ones. Similarly, all PACKAGES entries that do not correspond to any package tarball found in *dir* are considered invalid and are excluded from the resulting updated PACKAGES files.

When strict is TRUE, PACKAGES entries that match a package tarball (by package name and version) are confirmed via MD5 checksum; only those that pass are retained as valid. All novel package tarballs are fully processed by the standard machinery underlying [write\\_PACKAGES](#) and the resulting entries are added. Finally, if latestOnly is TRUE, package-version pruning is performed across the entries.

When strict is FALSE, package tarballs are assumed to encode correct metadata in their filenames. PACKAGES entries which appear to match a package tarball are retained as valid (No MD5 checksum testing occurs). If latestOnly is TRUE, package-version pruning is performed across the full set of retained entries and novel package tarballs *before* the processing of the novel tarballs, at significant computational and time savings in some situations. After the optional pruning, any relevant novel package tarballs are processed via the standard machinery and added to the set of retained entries.

In both cases, after the above process concludes, entries are sorted alphabetically by the string concatenation of Package and Version. This should match the entry order [write\\_PACKAGES](#) outputs.

The fields within the entries are ordered as follows: canonical fields - i.e., those appearing as columns when `available.packages` is called on a CRAN mirror - appear first in their canonical order, followed by any non-canonical fields.

After entry and field reordering, the final database of PACKAGES entries is written to all three PACKAGES files, overwriting the existing versions.

When `verbose.level` is 0, no extra messages are displayed to the user. When it is 1, detailed information about what is happening is conveyed via messages, but underlying machinery from `write_PACKAGES` is invoked with `verbose = FALSE`. Behavior when `verbose.level` is 2 is identical to `verbose.level` 1 with the exception that underlying machinery from `write_PACKAGES` is invoked with `verbose = TRUE`, which will individually list every processed tarball.

### Note

While both strict and non-strict modes can offer speedups when updating small percentages of large repositories, non-strict mode is *much* faster and is recommended in situations where the assumption it makes about tarballs' filenames encoding accurate information is safe.

### Note

Users should expect significantly smaller speedups over `write_PACKAGES` in the `type == "win.binary"` case on at least some operating systems. This is due to `write_PACKAGES` being significantly faster in this context, rather than `update_PACKAGES` being slower.

### Examples

```
## Not run:
write_PACKAGES("c:/myFolder/myRepository") # on Windows
update_PACKAGES("c:/myFolder/myRepository") # on Windows
write_PACKAGES("/pub/RWin/bin/windows/contrib/2.9",
  type = "win.binary") # on Linux
update_PACKAGES("/pub/RWin/bin/windows/contrib/2.9",
  type = "win.binary") # on Linux

## End(Not run)
```

---

update\_pkg\_po

---

*Prepare Translations for a Package*

---

### Description

Prepare the 'po' directory of a package and optionally compile and install the translations.

### Usage

```
update_pkg_po(pkgdir, pkg = NULL, version = NULL,
  pot_make = TRUE, mo_make = TRUE,
  verbose = getOption("verbose"),
  mergeOpts = "", copyright, bugs)
```

## Arguments

|                   |                                                                                                                                                                                                      |
|-------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| pkgdir            | The path to the package directory.                                                                                                                                                                   |
| pkg               | The package name: if NULL it is read from the package's 'DESCRIPTION' file.                                                                                                                          |
| version           | The package version: if NULL it is read from the package's 'DESCRIPTION' file.                                                                                                                       |
| pot_make, mo_make | <code>logicals</code> indicating if a new '*.pot' file or new binary translations '*.mo' should be (re)created.                                                                                      |
| verbose           | <code>logical</code> indicating if extra information about the updating process should be printed to the console.                                                                                    |
| mergeOpts         | a string, by default empty, of space-separated options to msgmerge in addition to "--update". Since R 4.2.0, "--no-wrap" is used when called from <code>file.path(R.home("po"), "Makefile")</code> . |
| copyright, bugs   | optional character strings for the 'Copyright' and 'Report-Msgid-Bugs-To' details in the template files.                                                                                             |

## Details

This performs a series of steps to prepare or update messages in the package.

- If the package sources do not already have a 'po' directory, one is created.
- `xgettext2pot` is called to create/update a file 'po/R-pkgname.pot' containing the translatable messages in the package.
- All existing files in directory po with names 'R-lang.po' are updated from 'R-pkgname.pot', `checkPoFile` is called on the updated file, and if there are no problems the file is compiled and installed under 'inst/po'.
- In a UTF-8 locale, a 'translation' 'R-en@quot.po' is created with UTF-8 directional quotes, compiled and installed under 'inst/po'.
- The remaining steps are done only if file 'po/pkgname.pot' already exists. The 'src/\*.c,cc,cpp,m,mm}' files in the package are examined to create a file 'po/pkgname.pot' containing the translatable messages in the C/C++ files. If there is a src/windows directory, files within it are also examined.
- All existing files in directory po with names 'lang.po' are updated from 'pkgname.pot', `checkPoFile` is called on the updated file, and if there are no problems the file is compiled and installed under 'inst/po'.
- In a UTF-8 locale, a 'translation' 'en@quot.po' is created with UTF-8 directional quotes, compiled and installed under 'inst/po'.

Note that C/C++ messages are not automatically prepared for translation as they need to be explicitly marked for translation in the source files. Once that has been done, create an empty file 'po/pkgname.pot' in the package sources and run this function again.

pkg = "base" is special (and for use by R developers only): the C files are not in the package directory but in the main sources.

## System requirements

This function requires the following tools from the GNU gettext-tools: xgettext, msgmerge, msgfmt, msginit and msgconv. These are part of most Linux distributions and easily compiled from the sources on Unix-alikes (including macOS). Pre-compiled versions for Windows are available in <https://www.stats.ox.ac.uk/pub/Rtools/goodies/gettext-tools.zip>.

It will probably not work correctly for en@quot translations except in a UTF-8 locale, so these are skipped elsewhere.

urltools

*Check Package URLs*

---

**Description**

Check URLs in package sources.

**Usage**

```
check_package_urls(dir, verbose = FALSE)
parse_URI_reference(x)
```

**Arguments**

|         |                                                                              |
|---------|------------------------------------------------------------------------------|
| dir     | a character string specifying the path to a package's root source directory. |
| verbose | a logical indicating if output should monitor check progress.                |
| x       | a character vector of URIs.                                                  |

**Details**

Checking URLs is performed in parallel using **curl** (so this must be installed for checking).

The URLs checked are extracted from the package 'DESCRIPTION' ('Description', 'URL' and 'BugReports' fields), Rd, 'CITATION' and 'NEWS.md' files, if package **xml2** is installed also from the '.html' files in 'inst/doc', and if additionally pandoc is available on the system the 'README.md' and 'NEWS.md' files.

For efficiency reasons, URLs are first checked using 'HEAD' requests, and the ones with non-OK (200) status codes re-checked via 'GET' requests (unfortunately, 'HEAD' requests are not always honored appropriately).

parse\_URI\_reference() is a helper which splits URI references into its scheme, authority, path, query and fragment parts. See RFC 3986 (<https://www.rfc-editor.org/rfc/rfc3986>) for more information.

**Value**

For check\_url\_db(), a data frame inheriting from class check\_url\_db with information on the URL check problems found.

For parse\_URI\_reference(), a data frame with character variables scheme, authority, path, query and fragment.

**Note**

This functionality is still experimental: interfaces may change in future versions.

## Examples

```
## Examples from RFC 3986.
parse_URI_reference(c("foo://example.com:8042/over/there?name=ferret#nose",
                     "urn:example:animal:ferret:nose",
                     "mailto:John.Doe@example.com",
                     "tel:+1-816-555-1212"))
```

---

userdir

*R User Directories*

---

## Description

Directories for storing R-related user-specific data, configuration and cache files.

## Usage

```
R_user_dir(package, which = c("data", "config", "cache"))
```

## Arguments

|         |                                                                                    |
|---------|------------------------------------------------------------------------------------|
| package | a character string giving the name of an R package                                 |
| which   | a character string indicating the kind of file(s) of interest. Can be abbreviated. |

## Details

For desktop environments using X Windows, the freedesktop.org project (formerly X Desktop Group, XDG) developed the XDG Base Directory Specification (<https://specifications.freedesktop.org/basedir-spec>) for standardizing the location where certain files should be placed. CRAN package **rappdirs** provides these general locations with appropriate values for all platforms for which R is available.

`R_user_dir` specializes the general mechanism to R package specific locations for user files, by providing package specific subdirectories inside a ‘R’ subdirectory inside the “base” directories appropriate for user-specific data, configuration and cache files (see the examples), with the intent that packages will not interfere if they work within their respective subdirectories.

The locations of these base directories can be customized via the specific environment variables `R_USER_DATA_DIR`, `R_USER_CONFIG_DIR` and `R_USER_CACHE_DIR`. If these are not set, the general XDG-style environment variables `XDG_DATA_HOME`, `XDG_CONFIG_HOME` and `XDG_CACHE_HOME` are used if set, and otherwise, defaults appropriate for the R platform in use are employed.

## Examples

```
R_user_dir("FOO", "cache")

## Create one, platform agnostically, must work if <normal> :
(Rdb <- R_user_dir("base"))
if(newD <- !dir.exists(Rdb)) # should work user specifically:
  newD <- dir.create(Rdb, recursive=TRUE)
dir(Rdb) # typically empty
if(newD) unlink(Rdb) # cleaning up

list.files(R_user_dir("grid"), full.names = TRUE)
```

vignetteEngine

*Set or Get a Vignette Processing Engine*

## Description

Vignettes are normally processed by [Sweave](#), but package writers may choose to use a different engine (e.g., one provided by the **knitr**, **noweb** or **R.rsp** packages). This function is used by those packages to register their engines, and internally by R to retrieve them.

## Usage

```
vignetteEngine(name, weave, tangle, pattern = NULL,
               package = NULL, aspell = list())
```

## Arguments

|         |                                                                                                                                                                                                             |
|---------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| name    | the name of the engine.                                                                                                                                                                                     |
| weave   | a function to convert vignette source files to PDF/HTML or intermediate LaTeX output.                                                                                                                       |
| tangle  | a function to convert vignette source files to R code.                                                                                                                                                      |
| pattern | a regular expression pattern for the filenames handled by this engine, or NULL for the default pattern.                                                                                                     |
| package | the package registering the engine. By default, this is the package calling vignetteEngine.                                                                                                                 |
| aspell  | a list with element names <code>filter</code> and/or <code>control</code> giving the respective arguments to be used when spell checking the text in the vignette source file with <a href="#">aspell</a> . |

## Details

If `weave` is missing, `vignetteEngine` will return the currently registered engine matching name and package.

If `weave` is NULL, the specified engine will be deleted.

Other settings define a new engine. The `weave` and `tangle` functions must be defined with argument lists compatible with `function(file, ...)`. Currently the ... arguments may include logical argument `quiet` and character argument `encoding`; others may be added in future. These are described in the documentation for [Sweave](#) and [Stangle](#).

The `weave` and `tangle` functions should return the filename of the output file that has been produced. Currently the `weave` function, when operating on a file named '`<name><pattern>`' must produce a file named '`<name>[.](tex|pdf|html)`'. The '`.tex`' files will be processed by `pdflatex` to produce '`.pdf`' output for display to the user; the others will be displayed as produced. The `tangle` function must produce a file named '`<name>[.][rRsS]`' containing the executable R code from the vignette. The `tangle` function may support a `split = TRUE` argument, and then it should produce files named '`<name>.*[.][rRsS]`'.

The `pattern` argument gives a regular expression to match the extensions of files which are to be processed as vignette input files. If set to NULL, the default pattern "`[.][RrSs](nw|tex)$`" is used.

**Value**

If the engine is being deleted, NULL. Otherwise a list containing components

|         |                                      |
|---------|--------------------------------------|
| name    | The name of the engine               |
| package | The name of its package              |
| pattern | The pattern for vignette input files |
| weave   | The weave function                   |
| tangle  | The tangle function                  |

str(vignetteEngine("Sweave"))
```

---

vignetteInfo

*Basic Information about a Vignette*

---

**Description**

Extract metadata from a vignette source file.

**Usage**

```
vignetteInfo(file)
```

**Arguments**

file                    file name of the vignette.

**Value**

A [list](#) with the following [character](#) components:

|          |                                                                                 |
|----------|---------------------------------------------------------------------------------|
| file     | the <a href="#">basename</a> of the file.                                       |
| title    | the vignette title from ‘\VignetteIndexEntry’, possibly an empty string.        |
| depends  | a vector of package dependencies from ‘\VignetteDepends’, possibly of length 0. |
| keywords | a vector of keywords from ‘\VignetteKeyword’, possibly of length 0.             |
| engine   | the <a href="#">vignetteEngine</a> , such as "utils::Sweave" or "knitr::knitr". |

**See Also**

[package\\_dependencies](#) for recursive dependencies.

**Examples**

```
gridEx <- system.file("doc", "grid.Rnw", package = "grid")
vi <- vignetteInfo(gridEx)
str(vi)
```

write\_PACKAGES

*Generate PACKAGES Files***Description**

Generate ‘PACKAGES’, ‘PACKAGES.gz’ and ‘PACKAGES.rds’ files for a repository of source or Mac/Windows binary packages.

**Usage**

```
write_PACKAGES(dir = ".", fields = NULL,
               type = c("source", "mac.binary", "win.binary"),
               verbose = FALSE, unpacked = FALSE, subdirs = FALSE,
               latestOnly = TRUE, addFiles = FALSE, rds_compress = "xz",
               validate = FALSE)
```

**Arguments**

|              |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|--------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| dir          | Character vector describing the location of the repository (directory including source or binary packages) to generate the ‘PACKAGES’, ‘PACKAGES.gz’ and ‘PACKAGES.rds’ files from and write them to.                                                                                                                                                                                                                                                                                                                                                            |
| fields       | a character vector giving the fields to be used in the ‘PACKAGES’, ‘PACKAGES.gz’ and ‘PACKAGES.rds’ files in addition to the default ones, or NULL (default).<br>The default corresponds to the fields needed by <a href="#">available.packages</a> : "Package", "Version", "Priority", "Depends", "Imports", "LinkingTo", "Suggests", "Enhances", "OS_type", "License" and "Archs", and those fields will always be included, plus the file name in field "File" if addFile = TRUE and the path to the subdirectory in field "Path" if subdirectories are used. |
| type         | Type of packages: currently source ‘.tar.{gz,bz2,xz,zstd}’ archives, and macOS or Windows binary (‘.tgz’ or ‘.zip’, respectively) packages are supported. Defaults to "win.binary" on Windows and to "source" otherwise.                                                                                                                                                                                                                                                                                                                                         |
| verbose      | logical. Should packages be listed as they are processed?                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| unpacked     | a logical indicating whether the package contents are available in unpacked form or not (default).                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| subdirs      | either logical (to indicate if subdirectories should be included, recursively) or a character vector of names of subdirectories to include (which are not recursed).                                                                                                                                                                                                                                                                                                                                                                                             |
| latestOnly   | logical: if multiple versions of a package are available should only the latest version be included?                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| addFiles     | logical: should the filenames be included as field ‘File’ in the ‘PACKAGES’ file.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| rds_compress | The type of compression to be used for ‘PACKAGES.rds’: see <a href="#">saveRDS</a> . The default is the one found to give maximal compression, and is as used on CRAN.                                                                                                                                                                                                                                                                                                                                                                                           |
| validate     | a logical indicating whether ‘DESCRIPTION’ files should be validated, and the corresponding packages skipped in case this finds problems.                                                                                                                                                                                                                                                                                                                                                                                                                        |

## Details

write\_PACKAGES scans the named directory for R packages, extracts information from each package's 'DESCRIPTION' file, and writes this information into the 'PACKAGES', 'PACKAGES.gz' and 'PACKAGES.rds' files, where the first two represent the information in DCF format, and the third serializes it via [saveRDS](#).

Including non-latest versions of packages is only useful if they have less constraining version requirements, so for example `latestOnly = FALSE` could be used for a source repository when 'foo\_1.0' depends on 'R >= 2.15.0' but 'foo\_0.9' is available which depends on 'R >= 2.11.0'.

Support for repositories with subdirectories and hence for `subdirs != FALSE` depends on recording a "Path" field in the 'PACKAGES' files.

Support for more general file names (e.g., other types of compression) *via* a "File" field in the 'PACKAGES' files can be used by [download.packages](#). If the file names are not of the standard form, use `addFiles = TRUE`.

`type = "win.binary"` uses [unz](#) connections to read all 'DESCRIPTION' files contained in the (zipped) binary packages for Windows in the given directory dir, and builds files 'PACKAGES', 'PACKAGES.gz' and 'PACKAGES.rds' files from this information.

For a remote repository there is a tradeoff between download speed and time spent by [available.packages](#) processing the downloaded file(s). For large repositories it is likely to be beneficial to use `rds_compress = "xz"`.

## Value

Invisibly returns the number of packages described in the resulting 'PACKAGES', 'PACKAGES.gz' and 'PACKAGES.rds' files. If 0, no packages were found and no files were written.

## Note

Processing '.tar.gz' archives to extract the 'DESCRIPTION' files is quite slow.

This function can be useful on other OSes to prepare a repository to be accessed by Windows machines, so `type = "win.binary"` should work on all OSes.

## Author(s)

Uwe Ligges and R-core.

## See Also

See [read.dcf](#) and [write.dcf](#) for reading 'DESCRIPTION' files and writing the 'PACKAGES' and 'PACKAGES.gz' files. See [update\\_PACKAGES](#) for efficiently updating existing 'PACKAGES' and 'PACKAGES.gz' files.

## Examples

```
## Not run:
write_PACKAGES("c:/myFolder/myRepository") # on Windows
write_PACKAGES("/pub/RWin/bin/windows/contrib/2.9",
               type = "win.binary") # on Linux

## End(Not run)
```

xgettext

*Extract Translatable Messages from R Files in a Package*

## Description

For each file in the ‘R’ directory (including system-specific subdirectories) of a *source* package, extract the unique arguments passed to these “message generating” calls;

**for** xgettext(): to [stop](#), [warning](#), [message](#), [packageStartupMessage](#), [gettext](#) and [gettextf](#),  
**for** xngettext(): to [ngettext](#).

xgettext2pot() calls both xgettext() and then xngettext().

## Usage

```
xgettext(dir, verbose = FALSE, asCall = TRUE)
```

```
xngettext(dir, verbose = FALSE)
```

```
xgettext2pot(dir, potFile, name = "R", version, bugs)
```

## Arguments

|                     |                                                                                                                                                                         |
|---------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| dir                 | the directory of a source package, i.e., with a ‘./R’ sub directory.                                                                                                    |
| verbose             | logical: should each file be listed as it is processed?                                                                                                                 |
| asCall              | logical: if TRUE each argument is converted to string and returned whole, otherwise the string literals within each argument are extracted (recursively). See Examples. |
| potFile             | name of po template file to be produced. Defaults to ‘R- <i>pkgname</i> .pot’ where <i>pkgname</i> is the basename of ‘dir’.                                            |
| name, version, bugs | as recorded in the template file: version defaults the version number of the currently running R, and bugs to “bugs.r-project.org”.                                     |

## Details

Leading and trailing white space (space, tab and linefeed (aka newline, i.e., ‘\n’)) is removed for all the calls extracted by xgettext(), see ‘Description’ above, as it is by the internal code that passes strings for translation.

We look to see if the matched functions were called with domain = NA. If so, when asCall is true, the whole call is omitted. Note that a call might contain a nested call to gettext (or warning, etc.) whose strings would be visible if asCall is false.

xgettext2pot calls xgettext and then xngettext, and writes a PO template file (to potFile) for use with the GNU gettext tools. This ensures that the strings for simple translation are unique in the file (as GNU gettext requires), but does not do so for ngettext calls (and the rules are not stated in the GNU gettext manual, but msgfmt complains if there is duplication between the sets.).

If applied to the **base** package, this also looks in the ‘.R’ files in ‘[R\\_HOME](#)/share/R’.

**Value**

For `xgettext`, a list of objects of class `"xgettext"` (which has a `print` method), one per source file that contains potentially translatable strings.

For `xngettext`, a list of objects of class `"xngettext"`, which are themselves lists of length-2 character vectors.

**See Also**

[update\\_pkg\\_po\(\)](#) which calls `xgettext2pot()`.

**Examples**

```
## Not run: ## in a source-directory build (not typical!) of R;
## otherwise, download and unpack the R sources, and replace
## R.home() by "<my_path_to_source_R>" :
xgettext(file.path(R.home(), "src", "library", "splines"))

## End(Not run)

## Create source package-like <tmp>/R/foo.R and get text from it:
tmpPkg <- tempdir()
tmpRDir <- file.path(tmpPkg, "R")
dir.create(tmpRDir, showWarnings = FALSE)
fnChar <- paste(sep = "\n",
  "foo <- function(x) {",
  "  if (x < -1) stop('too small')",
  "  # messages unduplicated (not so for ngettext)",
  "  if (x < -.5) stop('too small')",
  "  if (x < 0) {",
  "    warning(",
  "      'sqrt(x) is', sqrt(as.complex(x)),",
  "      ', which may be too small'",
  "    )",
  "  }",
  "  # calls with domain=NA are skipped",
  "  if (x == 0) cat(gettext('x is 0!\n', domain=NA))",
  "  # gettext strings may be ignored due to 'outer' domain=NA",
  "  if (x > 10) warning('x is ', gettextf('%0.2f', x), domain=NA)",
  "  # using a custom condition class",
  "  if (x == 42)",
  "    stop(errorCondition(gettext('needs Deep Thought'), class='myError'))",
  "  x",
  "}"
)

writeLines(fnChar, con = file.path(tmpRDir, "foo.R"))

## [[1]] : suppressing (tmpfile) name to make example Rdiff-able
xgettext(tmpPkg, asCall=TRUE)[[1]] # default; shows calls
xgettext(tmpPkg, asCall=FALSE)[[1]] # doesn't ; but then ' %0.2f '

unlink(tmpRDir, recursive=TRUE)
```

## Chapter 14

# The utils package

---

|               |                            |
|---------------|----------------------------|
| utils-package | <i>The R Utils Package</i> |
|---------------|----------------------------|

---

### Description

R utility functions

### Details

This package contains a collection of utility functions.

For a complete list, use `library(help = "utils")`.

### Author(s)

|-------|-------------------------------------|
| adist | <i>Approximate String Distances</i> |
|-------|-------------------------------------|

---

### Description

Compute the approximate string distance between character vectors. The distance is a generalized Levenshtein (edit) distance, giving the minimal possibly weighted number of insertions, deletions and substitutions needed to transform one string into another.

### Usage

```
adist(x, y = NULL, costs = NULL, counts = FALSE, fixed = TRUE,  
      partial = !fixed, ignore.case = FALSE, useBytes = FALSE)
```

## Arguments

|                          |                                                                                                                                                                                                                                                                                                       |
|--------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>           | a character vector. <a href="#">Long vectors</a> are not supported.                                                                                                                                                                                                                                   |
| <code>y</code>           | a character vector, or NULL (default) indicating taking <code>x</code> as <code>y</code> .                                                                                                                                                                                                            |
| <code>costs</code>       | a numeric vector or list with names partially matching ‘insertions’, ‘deletions’ and ‘substitutions’ giving the respective costs for computing the Levenshtein distance, or NULL (default) indicating using unit cost for all three possible transformations.                                         |
| <code>counts</code>      | a logical indicating whether to optionally return the transformation counts (numbers of insertions, deletions and substitutions) as the “counts” attribute of the return value.                                                                                                                       |
| <code>fixed</code>       | a logical. If TRUE (default), the <code>x</code> elements are used as string literals. Otherwise, they are taken as regular expressions and <code>partial = TRUE</code> is implied (corresponding to the approximate string distance used by <a href="#">agrep</a> with <code>fixed = FALSE</code> ). |
| <code>partial</code>     | a logical indicating whether the transformed <code>x</code> elements must exactly match the complete <code>y</code> elements, or only substrings of these. The latter corresponds to the approximate string distance used by <a href="#">agrep</a> (by default).                                      |
| <code>ignore.case</code> | a logical. If TRUE, case is ignored for computing the distances.                                                                                                                                                                                                                                      |
| <code>useBytes</code>    | a logical. If TRUE distance computations are done byte-by-byte rather than character-by-character.                                                                                                                                                                                                    |

## Details

The (generalized) Levenshtein (or edit) distance between two strings  $s$  and  $t$  is the minimal possibly weighted number of insertions, deletions and substitutions needed to transform  $s$  into  $t$  (so that the transformation exactly matches  $t$ ). This distance is computed for `partial = FALSE`, currently using a dynamic programming algorithm (see, e.g., [https://en.wikipedia.org/wiki/Levenshtein\\_distance](https://en.wikipedia.org/wiki/Levenshtein_distance)) with space and time complexity  $O(mn)$ , where  $m$  and  $n$  are the lengths of  $s$  and  $t$ , respectively. Additionally computing the transformation sequence and counts is  $O(\max(m, n))$ .

The generalized Levenshtein distance can also be used for approximate (fuzzy) string matching, in which case one finds the substring of  $t$  with minimal distance to the pattern  $s$  (which could be taken as a regular expression, in which case the principle of using the leftmost and longest match applies), see, e.g., [https://en.wikipedia.org/wiki/Approximate\\_string\\_matching](https://en.wikipedia.org/wiki/Approximate_string_matching). This distance is computed for `partial = TRUE` using ‘tre’ by Ville Laurikari (<https://github.com/laurikari/tre>) and corresponds to the distance used by [agrep](#). In this case, the given cost values are coerced to integer.

Note that the costs for insertions and deletions can be different, in which case the distance between  $s$  and  $t$  can be different from the distance between  $t$  and  $s$ .

## Value

A matrix with the approximate string distances of the elements of `x` and `y`, with rows and columns corresponding to `x` and `y`, respectively.

If `counts` is TRUE, the transformation counts are returned as the “counts” attribute of this matrix, as a 3-dimensional array with dimensions corresponding to the elements of `x`, the elements of `y`, and the type of transformation (insertions, deletions and substitutions), respectively. Additionally, if `partial = FALSE`, the transformation sequences are returned as the “trafos” attribute of the return value, as character strings with elements ‘M’, ‘I’, ‘D’ and ‘S’ indicating a match, insertion, deletion and substitution, respectively. If `partial = TRUE`, the offsets (positions of the first and last element)

of the matched substrings are returned as the "offsets" attribute of the return value (with both offsets -1 in case of no match).

### See Also

[agrep](#) for approximate string matching (fuzzy matching) using the generalized Levenshtein distance.

### Examples

```
## Cf. https://en.wikipedia.org/wiki/Levenshtein_distance
adist("kitten", "sitting")
## To see the transformation counts for the Levenshtein distance:
drop(attr(adist("kitten", "sitting", counts = TRUE), "counts"))
## To see the transformation sequences:
attr(adist(c("kitten", "sitting"), counts = TRUE), "trafos")

## Cf. the examples for agrep:
adist("lasy", "1 lazy 2")
## For a "partial approximate match" (as used for agrep):
adist("lasy", "1 lazy 2", partial = TRUE)
```

---

alarm

*Alert the User*

---

### Description

Gives an audible or visual signal to the user.

### Usage

```
alarm()
```

### Details

`alarm()` works by sending a "\a" character to the console. On most platforms this will ring a bell, beep, or give some other signal to the user (unless standard output has been redirected).

It attempts to flush the console (see [flush.console](#)).

### Value

No useful value is returned.

### Examples

```
alarm()
```

apropos

*Find Objects by (Partial) Name*

## Description

`apropos()` returns a character vector giving the names of objects in the search list matching (as a regular expression) `what`.

`find()` returns where objects of a given name can be found.

## Usage

```
apropos(what, where = FALSE, ignore.case = TRUE,
        dot_internals = FALSE, mode = "any")
```

```
find(what, mode = "any", numeric = FALSE, simple.words = TRUE)
```

## Arguments

|                             |                                                                                                                                                                                        |
|-----------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>what</code>           | a character string. For <code>find</code> with <code>simple.words = TRUE</code> , the name of an object; otherwise a <a href="#">regular expression</a> to match object names against. |
| <code>where, numeric</code> | logical indicating whether positions in the search list should also be returned.                                                                                                       |
| <code>ignore.case</code>    | logical indicating if the search should be case-insensitive, TRUE by default.                                                                                                          |
| <code>dot_internals</code>  | logical indicating if the search result should show <b>base</b> internal objects, FALSE by default.                                                                                    |
| <code>mode</code>           | a character string; if not "any", only objects whose <a href="#">mode</a> equals <code>mode</code> are searched.                                                                       |
| <code>simple.words</code>   | logical; if TRUE, the <code>what</code> argument is only searched as a whole word.                                                                                                     |

## Details

If `mode != "any"` only those objects which are of `mode` are considered.

`find` is a different user interface for a similar task to `apropos`. By default (`simple.words == TRUE`), only whole names are matched. Unlike `apropos`, matching is always case-sensitive.

Unlike the default behaviour of [ls](#), names which begin with a `'.'` are included, but base `'internal'` objects are included only when `dot_internals` is true.

## Value

For `apropos`, a character vector sorted by name. For `where = TRUE` this has names giving the (numerical) positions on the search path.

For `find`, either a character vector of environment names or (for `numeric = TRUE`) a numerical vector of positions on the search path with names the names of the corresponding environments.

## Author(s)

Originally, Kurt Hornik and Martin Maechler (May 1997).

aregexec

---

*Approximate String Match Positions*

---

**Description**

Determine positions of approximate string matches.

**Usage**

```
aregexec(pattern, text, max.distance = 0.1, costs = NULL,
          ignore.case = FALSE, fixed = FALSE, useBytes = FALSE)
```

## Arguments

|              |                                                                                                                                                                                                      |
|--------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| pattern      | a non-empty character string or a character string containing a regular expression (for <code>fixed = FALSE</code> ) to be matched. Coerced by <a href="#">as.character</a> to a string if possible. |
| text         | character vector where matches are sought. Coerced by <a href="#">as.character</a> to a character vector if possible.                                                                                |
| max.distance | maximum distance allowed for a match. See <a href="#">agrep</a> .                                                                                                                                    |
| costs        | cost of transformations. See <a href="#">agrep</a> .                                                                                                                                                 |
| ignore.case  | a logical. If TRUE, case is ignored for computing the distances.                                                                                                                                     |
| fixed        | If TRUE, the pattern is matched literally (as is). Otherwise (default), it is matched as a regular expression.                                                                                       |
| useBytes     | a logical. If TRUE comparisons are byte-by-byte rather than character-by-character.                                                                                                                  |

## Details

`aregexec` provides a different interface to approximate string matching than [agrep](#) (along the lines of the interfaces to exact string matching provided by [regexexec](#) and [grep](#)).

Note that by default, [agrep](#) performs literal matches, whereas `aregexec` performs regular expression matches.

See [agrep](#) and [adist](#) for more information about approximate string matching and distances.

Comparisons are byte-by-byte if pattern or any element of text is marked as "bytes".

## Value

A list of the same length as `text`, each element of which is either `-1` if there is no match, or a sequence of integers with the starting positions of the match and all substrings corresponding to parenthesized subexpressions of `pattern`, with attribute `"match.length"` an integer vector giving the lengths of the matches (or `-1` for no match).

## See Also

[regmatches](#) for extracting the matched substrings.

## Examples

```
## Cf. the examples for agrep.
x <- c("1 lazy", "1", "1 LAZY")
aregexec("lasy", x, max.distance = 2)
aregexec("(lay)(sy)", x, max.distance = 2)
aregexec("(lay)(sy)", x, max.distance = 2, ignore.case = TRUE)
m <- aregexec("(lay)(sy)", x, max.distance = 2)
regmatches(x, m)
```

---

arrangeWindows

*Rearrange Windows on MS Windows*

---

## Description

This function allows you to tile or cascade windows, or to minimize or restore them (on Windows, i.e. when (`.Platform$OS.type == "windows"`)). This may include windows not “belonging” to R.

## Usage

```
arrangeWindows(action, windows, preserve = TRUE, outer = FALSE)
```

## Arguments

|          |                                                                                                                                                                                                                                                    |
|----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| action   | a character string, the action to perform on the windows. The choices are <code>c("vertical", "horizontal", "cascade", "minimize", "restore")</code> with default "vertical"; see the ‘Details’ for the interpretation. Abbreviations may be used. |
| windows  | a <a href="#">list</a> of window handles, by default produced by <a href="#">getWindowsHandles()</a> .                                                                                                                                             |
| preserve | If TRUE, when tiling preserve the outer boundary of the collection of windows; otherwise make them as large as will fit.                                                                                                                           |
| outer    | This argument is only used in MDI mode. If TRUE, tile the windows on the system desktop. Otherwise, tile them within the MDI frame.                                                                                                                |

## Details

The actions are as follows:

"vertical" Tile vertically.

"horizontal" Tile horizontally.

"cascade" Cascade the windows.

"minimize" Minimize all of the windows.

"restore" Restore all of the windows to normal size (not minimized, not maximized).

The tiling and cascading are done by the standard Windows API functions, but unlike those functions, they will apply to all of the windows in the windows list.

By default, windows is set to the result of [getWindowsHandles\(\)](#) (with one exception described below). This will select windows belonging to the current R process. However, if the global environment contains a variable named `.arrangeWindowsDefaults`, it will be used as the argument list instead. See the [getWindowsHandles](#) man page for a discussion of the optional arguments to that function.

When `action = "restore"` is used with windows unspecified, `minimized = TRUE` is added to the argument list of [getWindowsHandles](#) so that minimized windows will be restored.

In MDI mode, by default tiling and cascading will happen within the R GUI frame. However, if `outer = TRUE`, tiling is done on the system desktop. This will generally not give desirable results if any R child windows are included within windows.

**Value**

This function is called for the side effect of arranging the windows. The list of window handles is returned invisibly.

**Note**

This is only available on Windows.

**Author(s)**

Duncan Murdoch

**See Also**

[getWindowsHandles](#)

**Examples**

```
## Not run: ## Only available on Windows :
arrangeWindows("v")
# This default is useful only in SDI mode: it will tile any Firefox window
# along with the R windows
.arrangeWindowsDefaults <- list(c("R", "all"), pattern = c("", "Firefox"))
arrangeWindows("v")

## End(Not run)
```

---

askYesNo

*Ask a Yes/No Question*

---

**Description**

askYesNo provides a standard way to ask the user a yes/no question. It provides a way for front-ends to substitute their own dialogs.

**Usage**

```
askYesNo(msg, default = TRUE,
         prompts = getOption("askYesNo", gettext(c("Yes", "No", "Cancel"))),
         ...)
```

**Arguments**

|         |                                                                                                                                                                                                            |
|---------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| msg     | The prompt message for the user.                                                                                                                                                                           |
| default | The default response.                                                                                                                                                                                      |
| prompts | Any of: a character vector containing 3 prompts corresponding to return values of TRUE, FALSE, or NA, or a single character value containing the prompts separated by / characters, or a function to call. |
| ...     | Additional parameters, ignored by the default function.                                                                                                                                                    |

Details

askYesNo will accept case-independent partial matches to the prompts. If no response is given the value of default will be returned; if a non-empty string that doesn't match any of the prompts is entered, an error will be raised.

If a function or single character string naming a function is given for prompts, it will be called as `fn(msg = msg, default = default, prompts = prompts, ...)`. On Windows, the GUI uses the unexported `utils::askYesNoWinDialog` function for this purpose.

If strings (or a string such as "Y/N/C") are given as prompts, the choices will be mapped to lower-case for the non-default choices, and left as-is for the default choice.

Value

TRUE for yes, FALSE for no, and NA for cancel.

See Also

`readline` for more general user input.

Examples

```
if (interactive())
  askYesNo("Do you want to use askYesNo?")
```

|--------|------------------------------|
| aspell | <i>Spell Check Interface</i> |
|--------|------------------------------|

---

Description

Spell check given files via Aspell, Hunspell or Ispell.

Usage

```
aspell(files, filter, control = list(), encoding = "unknown",
       program = NULL, dictionaries = character())
```

Arguments

- files            a character vector with the names of files to be checked.
- filter          an optional filter for processing the files before spell checking, given as either a function (with formals `ifile` and `encoding`), or a character string specifying a built-in filter, or a list with the name of a built-in filter and additional arguments to be passed to it. See **Details** for available filters. If missing or NULL, no filtering is performed.
- control        a list or character vector of control options for the spell checker.
- encoding       the encoding of the files. Recycled as needed.
- program        a character string giving the name (if on the system path) or full path of the spell check program to be used, or NULL (default). By default, the system path is searched for `aspell`, `hunspell` and `ispell` (in that order), and the first one found is used.

**dictionaries** a character vector of names or file paths of additional R level dictionaries to use. Elements with no path separator specify R system dictionaries (in subdirectory ‘share/dictionaries’ of the R home directory). The file extension (currently, only ‘.rds’) can be omitted.

## Details

The spell check programs employed must support the so-called Ispell pipe interface activated via command line option ‘-a’. In addition to the programs, suitable dictionaries need to be available. See <http://aspell.net>, <https://hunspell.github.io/> and <https://www.cs.hmc.edu/~geoff/ispell.html>, respectively, for obtaining the Aspell, Hunspell and (International) Ispell programs and dictionaries.

On Windows, Aspell is available via MSYS2. One should use a non-Cygwin version, e.g. package mingw-w64-x86\_64-aspell. The version built against the Cygwin runtime (package aspell) requires Unix line endings in files and Unix-style paths, which is incompatible with `aspell()`.

The currently available built-in filters are “Rd” (corresponding to [RdTextFilter](#), with additional argument `ignore` allowing to give regular expressions for parts of the text to be ignored for spell checking), “Sweave” (corresponding to [SweaveTeXFilter](#)), “R”, “pot”, “dcf” and “md”.

Filter “R” is for R code and extracts the message string constants in calls to [message](#), [warning](#), [stop](#), [packageStartupMessage](#), [gettext](#), [gettextf](#), and [ngettext](#) (the unnamed string constants for the first five, and `fmt` and `msg1/msg2` string constants, respectively, for the latter two).

Filter “pot” is for message string catalog ‘.pot’ files. Both have an argument `ignore` allowing to give regular expressions for parts of message strings to be ignored for spell checking: e.g., using “[\t]'[^']\*'[\t[:punct:]]” ignores all text inside single quotes.

Filter “dcf” is for files in Debian Control File format. The fields to keep can be controlled by argument `keep` (a character vector with the respective field names). By default, ‘Title’ and ‘Description’ fields are kept.

Filter “md” is for files in [Markdown](#) format (‘.md’ and ‘.Rmd’ files), and needs packages **common-mark** and **xml2** to be available.

The print method for the objects returned by `aspell` has an `indent` argument controlling the indentation of the positions of possibly misspelled words. The default is 2; Emacs users may find it useful to use an indentation of 0 and visit output in `grep-mode`. It also has a `verbose` argument: when this is true, suggestions for replacements are shown as well.

It is possible to employ additional R level dictionaries. Currently, these are files with extension ‘.rds’ obtained by serializing character vectors of word lists using [saveRDS](#). If such dictionaries are employed, they are combined into a single word list file which is then used as the spell checker’s personal dictionary (option ‘-p’): hence, the default personal dictionary is not used in this case.

## Value

A data frame inheriting from `aspell` (which has a useful print method) with the information about possibly misspelled words.

## Examples

```
## Not run:
## To check all Rd files in a directory, (additionally) skipping the
## \references sections.
files <- Sys.glob("*.Rd")
aspell(files, filter = list("Rd", drop = "\\references"))

## To check all Sweave files
files <- Sys.glob(c("*.Rnw", "*.Snw", "*.rnw", "*.snw"))
aspell(files, filter = "Sweave", control = "-t")

## To check all Texinfo files (Aspell only)
files <- Sys.glob("*.texi")
aspell(files, control = "--mode=texinfo")

## End(Not run)

## List the available R system dictionaries.
Sys.glob(file.path(R.home("share"), "dictionaries", "*.rds"))
```

aspell-utils

*Spell Check Utilities*

---

## Description

Utilities for spell checking packages via Aspell, Hunspell or Ispell.

## Usage

```
aspell_package_Rd_files(dir,
                        drop = c("\\abbr", "\\acronym",
                                "\\author", "\\references"),
                        control = list(), program = NULL,
                        dictionaries = character())
aspell_package_vignettes(dir,
                        control = list(), program = NULL,
                        dictionaries = character())
aspell_package_R_files(dir, ignore = character(), control = list(),
                      program = NULL, dictionaries = character())
aspell_package_C_files(dir, ignore = character(), control = list(),
                      program = NULL, dictionaries = character())

aspell_write_personal_dictionary_file(x, out, language = "en",
                                     program = NULL)
```

## Arguments

|         |                                                                                                                 |
|---------|-----------------------------------------------------------------------------------------------------------------|
| dir     | a character string specifying the path to a package's root directory.                                           |
| drop    | a character vector naming additional Rd sections to drop when selecting text via <a href="#">RdTextFilter</a> . |
| control | a list or character vector of control options for the spell checker.                                            |

|              |                                                                                                                                                                                                                                                                                                     |
|--------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| program      | a character string giving the name (if on the system path) or full path of the spell check program to be used, or NULL (default). By default, the system path is searched for <code>aspell</code> , <code>hunspell</code> and <code>ispell</code> (in that order), and the first one found is used. |
| dictionaries | a character vector of names or file paths of additional R level dictionaries to use. See <a href="#">aspell</a> .                                                                                                                                                                                   |
| ignore       | a character vector with regular expressions to be replaced by blanks when filtering the message strings.                                                                                                                                                                                            |
| x            | a character vector, or the result of a call to <a href="#">aspell()</a> .                                                                                                                                                                                                                           |
| out          | a character string naming the personal dictionary file to write to.                                                                                                                                                                                                                                 |
| language     | a character string indicating a language as used by Aspell.                                                                                                                                                                                                                                         |

## Details

Functions `aspell_package_Rd_files`, `aspell_package_vignettes`, `aspell_package_R_files` and `aspell_package_C_files` perform spell checking on the Rd files, vignettes, R files, and C-level messages of the package with root directory `dir`. They determine the respective files, apply the appropriate filters, and run the spell checker.

See [aspell](#) for details on filters.

The C-level message string are obtained from the `'po/PACKAGE.pot'` message catalog file, with `PACKAGE` the basename of `dir`. See the section on 'C-level messages' in 'Writing R Extensions' for more information.

When using Aspell, the vignette checking skips parameters and/or options of commands `\Sexpr`, `\citep`, `\code`, `\pkg`, `\proglang` and `\samp` (in addition to the what the Aspell TeX/L<sup>A</sup>T<sub>E</sub>X filter skips by default). Further commands can be skipped by adding `--add-tex-command` options to the control argument. E.g., to skip both option and parameter of `\mycmd`, add `--add-tex-command='mycmd op'`.

Suitable values for control, program, dictionaries, drop and ignore can also be specified using a package defaults file which should go as `'defaults.R'` into the `'.aspell'` subdirectory of `dir`, and provides defaults via assignments of suitable named lists, e.g.,

```
vignettes <- list(control = "--add-tex-command='mycmd op'")
```

for vignettes (when using Aspell) and similarly assigning to `Rd_files`, `R_files` and `C_files` for Rd files, R files and C level message defaults.

Maintainers of packages using both English and American spelling will find it convenient to pass control options `--master=en_US` and `--add-extra-dicts=en_GB` to Aspell and control options `-d en_US,en_GB` to Hunspell (provided that the corresponding dictionaries are installed).

Older versions of R had no support for R level dictionaries, and hence provided the function `aspell_write_personal_dictionary_file` to create (spell check) program-specific personal dictionary files from words to be accepted. The new mechanism is to use R level dictionaries, i.e., `'.rds'` files obtained by serializing character vectors of such words using [saveRDS](#). For such dictionaries specified via the package defaults mechanism, elements with no path separator can be R system dictionaries or dictionaries in the `'.aspell'` subdirectory.

|--------------------|----------------------------------------------------------|
| available.packages | <i>List Available Packages at CRAN-like Repositories</i> |
|--------------------|----------------------------------------------------------|

---

## Description

`available.packages` returns a matrix of details corresponding to packages currently available at one or more repositories. The current list of packages is downloaded over the internet (or copied from a local mirror).

## Usage

```
available.packages(contriburl = contrib.url(repos, type), method,
                  fields = getOption("available_packages_fields"),
                  type = getOption("pkgType"), filters = NULL,
                  repos = getOption("repos"),
                  ignore_repo_cache = FALSE, max_repo_cache_age,
                  cache_user_dir =
                    str2logical(Sys.getenv("R_PACKAGES_CACHE_USER_DIR",
                                           FALSE))),
                  quiet = TRUE, verbose = FALSE, ...)
```

## Arguments

|                                 |                                                                                                                                                                                          |
|---------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>contriburl</code>         | URL(s) of the ‘contrib’ sections of the repositories. Specify this argument only if your repository mirror is incomplete, e.g., because you mirrored only the ‘contrib’ section.         |
| <code>method</code>             | download method, see <a href="#">download.file</a> .                                                                                                                                     |
| <code>type</code>               | character string, indicate which type of packages: see <a href="#">install.packages</a> . If <code>type = "both"</code> this will use the source repository.                             |
| <code>fields</code>             | a character vector giving the fields to extract from the ‘PACKAGES’ file(s) in addition to the default ones, or NULL (default). Unavailable fields result in NA values.                  |
| <code>filters</code>            | a character vector or list or NULL (default). See ‘Details’.                                                                                                                             |
| <code>repos</code>              | character vector, the base URL(s) of the repositories to use.                                                                                                                            |
| <code>ignore_repo_cache</code>  | logical. If true, the repository cache is never used (see ‘Details’).                                                                                                                    |
| <code>max_repo_cache_age</code> | any cached values older than this in seconds will be ignored. See ‘Details’.                                                                                                             |
| <code>cache_user_dir</code>     | <a href="#">logical</a> indicating if caching should happen in <b>tools’</b> <code>R_user_dir("base", "cache")</code> instead of <code>tempdir()</code> .                                |
| <code>quiet</code>              | logical, passed to <a href="#">download.file()</a> ; change only if you know what you are doing.                                                                                         |
| <code>verbose</code>            | logical indicating if a “progress report” line should be printed about the number of packages found in each repository.                                                                  |
| <code>...</code>                | allow additional arguments to be passed from callers (which might be arguments to future versions of this function). Currently these are all passed to <a href="#">download.file()</a> . |

## Details

The list of packages is either copied from a local mirror (specified by a ‘file://’ URI) or downloaded. If downloaded and `ignore_repo_cache` is false (the default), the list is cached for the R session in a per-repository file in `tempdir()` with a name like

```
repos_http%3a%2f%2fcran.r-project.org%2fsrc%2fcontrib.rds
```

The cached values are renewed when found to be too old, with the age limit controlled *via* argument `max_repo_cache_age`. This defaults to the current value of the environment variable `R_AVAILABLE_PACKAGES_CACHE_CONTROL_MAX_AGE`, or if unset, to 3600 (one hour).

By default, the return value includes only packages whose version and OS requirements are met by the running version of R, and only gives information on the latest versions of packages.

Argument `filters` can be used to select which of the packages on the repositories are reported. It is called with its default value (NULL) by functions such as `install.packages`: this value corresponds to `getOption("available_packages_filters")` and to `c("R_version", "OS_type", "subarch", "duplicates")` if that is unset or set to NULL.

The built-in filters are

"R\_version" Exclude packages whose R version requirements are not met.

"OS\_type" Exclude packages whose OS requirement is incompatible with this version of R: that is exclude Windows-only packages on a Unix-alike platform and *vice versa*.

"subarch" For binary packages, exclude those with compiled code that is not available for the current sub-architecture, e.g. exclude packages only compiled for 32-bit Windows on a 64-bit Windows R.

"duplicates" Only report the latest version where more than one version is available, and only report the first-named repository (in `contriburl`) with the latest version if that is in more than one repository.

"license/FOSS" Include only packages for which installation can proceed solely based on packages which can be verified as Free or Open Source Software (FOSS, e.g., <https://en.wikipedia.org/wiki/FOSS>) employing the available license specifications. Thus both the package and any packages that it depends on to load need to be *known to be* FOSS.

Note that this does depend on the repository supplying license information.

"license/restricts\_use" Include only packages for which installation can proceed solely based on packages which are known not to restrict use.

"CRAN" Use CRAN versions in preference to versions from other repositories (even if these have a higher version number). This needs to be applied *before* the default "duplicates" filter, so cannot be used with `add = TRUE`.

If all the filters are from this set, then they can be specified as a character vector; otherwise filters should be a list with elements which are character strings, user-defined functions or `add = TRUE` (see below).

User-defined filters are functions which take a single argument, a matrix of the form returned by `available.packages`, and return a matrix consisting of a subset of the rows of the argument.

The special ‘filter’ `add = TRUE` appends the other elements of the filter list to the default filters.

## Value

A character matrix with one row per package, row names the package names and column names including "Package", "Version", "Priority", "Depends", "Imports", "LinkingTo",

"Suggests", "Enhances", "File" and "Repository". Additional columns can be specified using the `fields` argument.

Where provided by the repository, fields "OS\_type", "License", "License\_is\_FOSS", "License\_restricts\_use", "Archs", "MD5sum" and "NeedsCompilation" are reported for use by the filters and package management tools, including [install.packages](#).

### See Also

[packageStatus](#), [update.packages](#), [install.packages](#), [download.packages](#), [contrib.url](#).

The 'R Installation and Administration' manual for how to set up a repository.

### Examples

```
## Count package licenses
db <- available.packages(repos = findCRANmirror("web"), filters = "duplicates")
table(db[, "License"])

## Use custom filter function to only keep recommended packages
## which do not require compilation
available.packages(repos = findCRANmirror("web"),
  filters = list(
    add = TRUE,
    function (db) db[db[, "Priority"] %in% "recommended" &

---

BATCH

*Batch Execution of R*

---

### Description

Run R non-interactively with input from `infile` and send output (`stdout/stderr`) to another file.

### Usage

R CMD BATCH [options] infile [outfile]

**Arguments**

|                      |                                                                                                                                                                                                                                                                                                   |
|----------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>infile</code>  | the name of a file with R code to be executed.                                                                                                                                                                                                                                                    |
| <code>options</code> | a list of R command line options, e.g., for setting the amount of memory available and controlling the load/save process. If <code>infile</code> starts with a '-', use '--' as the final option. The default options are '--restore --save --no-readline'. (Without '--no-readline' on Windows.) |
| <code>outfile</code> | the name of a file to which to write output. If not given, the name used is that of <code>infile</code> , with a possible '.R' extension stripped, and '.Rout' appended.                                                                                                                          |

**Details**

Use R CMD BATCH --help to be reminded of the usage.

By default, the input commands are printed along with the output. To suppress this behavior, add `options(echo = FALSE)` at the beginning of `infile`, or use option '--no-echo'.

The `infile` can have end of line marked by LF or CRLF (but not just CR), and files with an incomplete last line (missing end of line (EOL) mark) are processed correctly.

A final expression '`proc.time()`' will be executed after the input script unless the latter calls `q(runLast = FALSE)` or is aborted. This can be suppressed by the option '--no-timing'.

Additional options can be set by the environment variable `R_BATCH_OPTIONS`: these come after the default options (see the description of the options argument) and before any options given on the command line.

**Note**

On Unix-alikes only: Unlike Splus BATCH, this does not run the R process in the background. In most shells,

```
R CMD BATCH [options] infile [outfile] &
```

will do so.

---

bibentry

*Bibliography Entries*

---

**Description**

Functionality for representing and manipulating bibliographic information in enhanced BibTeX style.

**Usage**

```
bibentry(bibtype, textVersion = NULL, header = NULL, footer = NULL,
         key = NULL, ..., other = list(),
         mheader = NULL, mfooter = NULL)

## S3 method for class 'bibentry'
print(x, style = "text", .bibstyle,
      bibtex = length(x) <= getOption("citation.bibtex.max", 1),
      ...)
```

```
## S3 method for class 'bibentry'
format(x, style = "text", .bibstyle = NULL,
       bibtex = length(x) <= 1,
       citMsg = missing(bibtex),
       sort = FALSE, macros = NULL, ...)

## S3 method for class 'bibentry'
sort(x, decreasing = FALSE, .bibstyle = NULL, drop = FALSE, ...)

## S3 method for class 'citation'
print(x, style = "citation", ...)
## S3 method for class 'citation'
format(x, style = "citation", ...)

## S3 method for class 'bibentry'
toBibtex(object, escape = FALSE, ...)
```

## Arguments

|                          |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|--------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>bibtype</code>     | a character string with a BibTeX entry type. See <b>Entry Types</b> for details.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <code>textVersion</code> | a character string with a text representation of the reference to optionally be employed for printing. It is recommended to leave this unspecified if <code>format(x, style = "text")</code> works correctly. Only if special LaTeX macros (e.g., math formatting) or special characters (e.g., with accents) are necessary, a <code>textVersion</code> should be provided.                                                                                                                                                                                                                                                                                                        |
| <code>header</code>      | a character string with optional header text.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <code>footer</code>      | a character string with optional footer text.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <code>key</code>         | a character string giving the citation key for the entry.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <code>...</code>         | for <code>bibentry</code> : arguments of the form <code>tag=value</code> giving the fields of the entry, with <code>tag</code> and <code>value</code> the name and value of the field, respectively. Arguments with empty values are dropped. Field names are case-insensitive. See <b>Entry Fields</b> for details.<br><br>For the <code>print()</code> method, extra arguments to pass to the renderer which typically includes the <code>format()</code> method.<br><br>For the <code>citation</code> class methods, arguments passed to the next method, i.e., the corresponding <code>bibentry</code> one.<br><br>For the <code>toBibtex()</code> method, currently not used. |
| <code>other</code>       | a list of arguments as in <code>...</code> (useful in particular for fields named the same as <code>formals</code> of <code>bibentry</code> ).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <code>mheader</code>     | a character string with optional “outer” header text.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <code>mfooter</code>     | a character string with optional “outer” footer text.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <code>x</code>           | an object inheriting from class <code>"bibentry"</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <code>style</code>       | an optional character string specifying the print style. If present, must be a unique abbreviation (with case ignored) of the available styles, see <b>Details</b> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <code>decreasing</code>  | logical, passed to <code>order</code> indicating the sort direction.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <code>.bibstyle</code>   | a character string naming a bibliography style, see <code>bibstyle</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

|                     |                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|---------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>bibtex</code> | <code>logical</code> indicating if BibTeX code should be given additionally; currently applies only to <code>style = "citation"</code> . The default for the <code>print()</code> method depends on the number of (bib) entries and <code>getOption("citation.bibtex.max")</code> (which itself is 1 by default). For example, to see no BibTeX at all, you can change the default by <code>options(citation.bibtex.max = 0)</code> . |
| <code>citMsg</code> | <code>logical</code> indicating if a “message” should be added (to the footer) about how to get BibTeX code when <code>bibtex</code> is false <i>and</i> <code>style = "citation"</code> .                                                                                                                                                                                                                                            |
| <code>sort</code>   | <code>logical</code> indicating if bibentries should be sorted, using <code>bibstyle(.bibstyle)\$sortKeys(x)</code> .                                                                                                                                                                                                                                                                                                                 |
| <code>macros</code> | a character string or an object with already loaded Rd macros, see <b>Details</b> .                                                                                                                                                                                                                                                                                                                                                   |
| <code>drop</code>   | <code>logical</code> used as <code>x[ ..., drop=drop]</code> inside the <code>sort()</code> method.                                                                                                                                                                                                                                                                                                                                   |
| <code>object</code> | an object inheriting from class <code>"bibentry"</code> .                                                                                                                                                                                                                                                                                                                                                                             |
| <code>escape</code> | a logical indicating whether non-ASCII characters should be translated to LaTeX escape sequences.                                                                                                                                                                                                                                                                                                                                     |

## Details

The `bibentry` objects created by `bibentry` can represent an arbitrary positive number of references. One can use `c()` to combine `bibentry` objects, and hence in particular build a multiple reference object from single reference ones. Alternatively, one can use `bibentry` to directly create a multiple reference object by specifying the arguments as lists of character strings.

The `print` method for `bibentry` objects is based on a corresponding `format` method and provides a choice between seven different styles: plain text (`style "text"`), BibTeX (`"bibtex"`), a mixture of plain text and BibTeX as traditionally used for citations (`"citation"`), HTML (`"html"`), L<sup>A</sup>T<sub>E</sub>X (`"latex"`), R code (`"R"`), and a simple copy of the `textVersion` elements (`style "textVersion"`).

The `"text"`, `"html"` and `"latex"` styles make use of the `.bibstyle` argument: a style defined by the `bibstyle` function for rendering the `bibentry` into (intermediate) Rd format. The Rd format uses markup commands documented in the ‘Rd format’ section of the ‘Writing R Extensions’ manual, e.g. `\bold`. In addition, one can use the `macros` argument to provide additional (otherwise unknown, presumably LaTeX-style) Rd macros, either by giving the path to a file with Rd macros to be loaded via `loadRdMacros`, or an object with macros already loaded. Note that the `"latex"` result may contain commands from the L<sup>A</sup>T<sub>E</sub>X style file ‘Rd.sty’ shipped with R; put `\usepackage{Rd}` in the preamble of a LaTeX document to make these available when compiling, e.g. with `texi2pdf`.

When printing `bibentry` objects in citation style, a header/footer for each item can be displayed as well as a `mheader/mfooter` for the whole vector of references.

For formatting as R code, a choice between giving a character vector with one `bibentry()` call for each `bibentry` (as commonly used in ‘CITATION’ files), or a character string with one collapsed call, obtained by combining the individual calls with `c()` if there is more than one `bibentry`. This can be controlled by passing the argument `collapse=FALSE` (default) or `TRUE`, respectively, to the `format()` method. (*Printing* in R style always collapses to a single call.)

It is possible to subscript `bibentry` objects by their keys (which are used for character subscripts if the names are `NULL`).

There is also a `toBibtex` method for direct conversion to BibTeX.

As of R 4.3.0, there is also a `transform` method which allows to directly use the current fields, see the examples.

## Value

`bibentry` produces an object of class `"bibentry"`.

## Entry Types

bibentry creates "bibentry" objects, which are modeled after BibTeX entries. The entry should be a valid BibTeX entry type, e.g.,

**Article:** An article from a journal or magazine.

**Book:** A book with an explicit publisher.

**InBook:** A part of a book, which may be a chapter (or section or whatever) and/or a range of pages.

**InCollection:** A part of a book having its own title.

**InProceedings:** An article in a conference proceedings.

**Manual:** Technical documentation like a software manual.

**MastersThesis:** A Master's thesis.

**Misc:** Use this type when nothing else fits.

**PhdThesis:** A PhD thesis.

**Proceedings:** The proceedings of a conference.

**TechReport:** A report published by a school or other institution, usually numbered within a series.

**Unpublished:** A document having an author and title, but not formally published.

## Entry Fields

The ... argument of bibentry can be any number of BibTeX fields, including

**address:** The address of the publisher or other type of institution.

**author:** The name(s) of the author(s), either as a [person](#) object, or as a character string which [as.person](#) correctly coerces to such.

**booktitle:** Title of a book, part of which is being cited.

**chapter:** A chapter (or section or whatever) number.

**doi:** The DOI ([https://en.wikipedia.org/wiki/Digital\\_Object\\_Identifier](https://en.wikipedia.org/wiki/Digital_Object_Identifier)) for the reference.

**editor:** Name(s) of editor(s), same format as author.

**institution:** The publishing institution of a technical report.

**journal:** A journal name.

**note:** Any additional information that can help the reader. The first word should be capitalized.

**number:** The number of a journal, magazine, technical report, or of a work in a series.

**pages:** One or more page numbers or range of numbers.

**publisher:** The publisher's name.

**school:** The name of the school where a thesis was written.

**series:** The name of a series or set of books.

**title:** The work's title.

**url:** A URL for the reference. (If the URL is an expanded DOI, we recommend to use the 'doi' field with the unexpanded DOI instead.)

**volume:** The volume of a journal or multi-volume book.

**year:** The year of publication.

**See Also**[person](#)**Examples**

```
## R reference
rref <- bibentry(
  bibtype = "Manual",
  title = "R: A Language and Environment for Statistical Computing",
  author = person("R Core Team"),
  organization = "R Foundation for Statistical Computing",
  address = "Vienna, Austria",
  year = 2014,
  url = "https://www.R-project.org/")

## Different printing styles
print(rref)
print(rref, style = "bibtex")
print(rref, style = "citation")
print(rref, style = "html")
print(rref, style = "latex")
print(rref, style = "R")

## References for boot package and associated book
bref <- c(
  bibentry(
    bibtype = "Manual",
    title = "boot: Bootstrap R (S-PLUS) Functions",
    author = c(
      person("Angelo", "Canty", role = "aut",
        comment = "S original"),
      person(c("Brian", "D."), "Ripley", role = c("aut", "trl", "cre"),
        comment = "R port, author of parallel support",
        email = "ripley@stats.ox.ac.uk")
    ),
    year = "2012",
    note = "R package version 1.3-4",
    url = "https://CRAN.R-project.org/package=boot",
    key = "boot-package"
  ),
  bibentry(
    bibtype = "Book",
    title = "Bootstrap Methods and Their Applications",
    author = as.person("Anthony C. Davison [aut], David V. Hinkley [aut]"),
    year = "1997",
    publisher = "Cambridge University Press",
    address = "Cambridge",
    isbn = "0-521-57391-2",
    url = "http://statwww.epfl.ch/davison/BMA/",
    key = "boot-book"
  )
)

## Combining and subsetting
c(rref, bref)
```

```

bref[2]
bref["boot-book"]

## Extracting fields
bref$author
bref[1]$author
bref[1]$author[2]$email

## Field names are case-insensitive
rref$Year
rref$Year <- R.version$year
stopifnot(identical(rref$year, R.version$year))

## Convert to BibTeX
toBibtex(bref)

## Transform
transform(rref, address = paste0(address, ", Europe"))

## BibTeX reminder message (in case of >= 2 refs):
print(bref, style = "citation")

## Format in R style
## One bibentry() call for each bibentry:
writelines(paste(format(bref, "R"), collapse = "\n\n"))
## One collapsed call:
writelines(format(bref, "R", collapse = TRUE))

```

---

browseEnv

*Browse Objects in Environment*

---

## Description

The `browseEnv` function opens a browser with list of objects currently in `sys.frame()` environment.

## Usage

```

browseEnv(envir = .GlobalEnv, pattern,
          excludepatt = "^last\\.warning",
          html = .Platform$GUI != "AQUA",
          expanded = TRUE, properties = NULL,
          main = NULL, debugMe = FALSE)

```

## Arguments

|                          |                                                                                                                                                                         |
|--------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>envir</code>       | an <a href="#">environment</a> the objects of which are to be browsed.                                                                                                  |
| <code>pattern</code>     | a <a href="#">regular expression</a> for object subselection is passed to the internal <code>ls()</code> call.                                                          |
| <code>excludepatt</code> | a regular expression for <i>dropping</i> objects with matching names.                                                                                                   |
| <code>html</code>        | is used to display the workspace on a HTML page in your favorite browser. The default except when running from R. app on macOS.                                         |
| <code>expanded</code>    | whether to show one level of recursion. It can be useful to switch it to FALSE if your workspace is large. This option is ignored if <code>html</code> is set to FALSE. |

|            |                                                                                                                                                                 |
|------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| properties | a named list of global properties (of the objects chosen) to be showed in the browser; when NULL (as per default), user, date, and machine information is used. |
| main       | a title string to be used in the browser; when NULL (as per default) a title is constructed.                                                                    |
| debugMe    | logical switch; if true, some diagnostic output is produced.                                                                                                    |

### Details

Very experimental code: displays a static HTML page on all platforms except R. app on macOS.

Only allows one level of recursion into object structures.

It can be generalized. See sources for details. Most probably, this should rather work through using the **tkWidget** package (from <https://www.bioconductor.org>).

### Examples

```
if(interactive()) {
  ## create some interesting objects :
  ofa <- ordered(4:1)
  ex1 <- expression(1+ 0:9)
  ex3 <- expression(u, v, 1+ 0:9)
  example(factor, echo = FALSE)
  example(table, echo = FALSE)
  example(ftable, echo = FALSE)
  example(lm, echo = FALSE, ask = FALSE)
  example(str, echo = FALSE)

  ## and browse them:
  browseEnv()

  ## a (simple) function's environment:
  af12 <- approxfun(1:2, 1:2, method = "const")
  browseEnv(envir = environment(af12))
}
```

---

browseURL

*Load URL into an HTML Browser*

---

### Description

Load a given URL into an HTML browser.

### Usage

```
browseURL(url, browser = getOption("browser"),
          encodeIfNeeded = FALSE,
          verbose = getOption("verbose"))
```

## Arguments

|                |                                                                                                                                                                                                                                                                                                                                                  |
|----------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| url            | a non-empty character string giving the URL to be loaded. Some platforms also accept file paths.                                                                                                                                                                                                                                                 |
| browser        | a non-empty character string giving the name of the program to be used as the HTML browser. It should be in the PATH, or a full path specified. Alternatively, an R function to be called to invoke the browser.<br>Under Windows NULL is also allowed (and is the default), and implies that the file association mechanism will be used.       |
| encodeIfNeeded | Should the URL be encoded by <a href="#">URLencode</a> before passing to the browser? This is not needed (and might be harmful) if the browser program/function itself does encoding, and can be harmful for 'file://' URLs on some systems and for 'http://' URLs passed to some CGI applications. Fortunately, most URLs do not need encoding. |
| verbose        | logical indicating if information about the system interface should be printed to the console.                                                                                                                                                                                                                                                   |

## Details

**On Unix-alikes:** The default browser is set by option "browser", in turn set by the environment variable R\_BROWSER which is by default set in file '[R\\_HOME](#)/etc/Renviron' to a choice made manually or automatically when R was configured. (See [Startup](#) for where to override that default value.) To suppress showing URLs altogether, use the value "false".

On many platforms it is best to set option "browser" to a generic program/script and let that invoke the user's choice of browser. For example, on macOS use open and on many other Unix-alikes use xdg-open.

If browser supports remote control and R knows how to perform it, the URL is opened in any already-running browser or a new one if necessary. This mechanism currently is available for browsers which support the "-remote openURL(...)" interface (which includes Mozilla and Opera), Epiphany, KDE konqueror (*via* kfmclient) and the GNOME interface to Mozilla. (Firefox has dropped support, but defaults to using an already-running browser.) Note that the type of browser is determined from its name, so this mechanism will only be used if the browser is installed under its canonical name.

Because "-remote" will use any browser displaying on the X server (whatever machine it is running on), the remote control mechanism is only used if DISPLAY points to the local host. This may not allow displaying more than one URL at a time from a remote host.

It is the caller's responsibility to encode url if necessary (see [URLencode](#)).

To suppress showing URLs altogether, set browser = "false".

The behaviour for arguments url which are not URLs is platform-dependent. Some platforms accept absolute file paths; fewer accept relative file paths.

**On Windows:** The default browser is set by option "browser", in turn set by the environment variable R\_BROWSER if that is set, otherwise to NULL. To suppress showing URLs altogether, use the value "false".

Some browsers have required ':' be replaced by '|' in file paths: others do not accept that. All seem to accept '\' as a path separator even though the RFC1738 standard requires '/'. To suppress showing URLs altogether, set browser = "false".

## URL schemes

Which URL schemes are accepted is platform-specific: expect 'http://', 'https://' and 'ftp://' to work, but 'mailto:' may or may not (and if it does may not use the user's preferred email client). However, modern browsers are unlikely to handle 'ftp://'.

For the ‘file://’ scheme the format accepted (if any) can depend on both browser and OS.

### Examples

```
## Not run:
## for KDE users who want to open files in a new tab
options(browser = "kfmclient newTab")

browseURL("https://www.r-project.org")

## On Windows-only, something like
browseURL("file://d:/R/R-2.5.1/doc/html/index.html",
          browser = "C:/Program Files/Mozilla Firefox/firefox.exe")

## End(Not run)
```

---

browseVignettes

*List Vignettes in an HTML Browser*

---

### Description

List available vignettes in an HTML browser with links to PDF, LaTeX/Noweb source, and (tangled) R code (if available).

### Usage

```
browseVignettes(package = NULL, lib.loc = NULL, all = TRUE)

## S3 method for class 'browseVignettes'
print(x, ...)
```

### Arguments

|         |                                                                                                                                             |
|---------|---------------------------------------------------------------------------------------------------------------------------------------------|
| package | a character vector with the names of packages to search through, or NULL in which "all" packages (as defined by argument all) are searched. |
| lib.loc | a character vector of directory names of R libraries, or NULL. The default value of NULL corresponds to all libraries currently known.      |
| all     | logical; if TRUE search all available packages in the library trees specified by lib.loc, and if FALSE, search only attached packages.      |
| x       | Object of class browseVignettes.                                                                                                            |
| ...     | Further arguments, ignored by the print method.                                                                                             |

### Details

Function browseVignettes returns an object of the same class; the print method displays it as an HTML page in a browser (using [browseURL](#)).

### See Also

[browseURL](#), [vignette](#)

**Examples**

```
## List vignettes from all *attached* packages
browseVignettes(all = FALSE)

## List vignettes from a specific package
browseVignettes("grid")
```

bug.report

*Send a Bug Report***Description**

Invokes an editor or email program to write a bug report or opens a web page for bug submission. Some standard information on the current version and configuration of R are included automatically.

**Usage**

```
bug.report(subject = "", address,
           file = "R.bug.report", package = NULL, lib.loc = NULL,
           ...)
```

**Arguments**

|         |                                                                                                                                                                                    |
|---------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| subject | Subject of the email.                                                                                                                                                              |
| address | Recipient's email address, where applicable: for package bug reports sent by email this defaults to the address of the package maintainer (the first if more than one is listed).  |
| file    | filename to use (if needed) for setting up the email.                                                                                                                              |
| package | Optional character vector naming a single package which is the subject of the bug report.                                                                                          |
| lib.loc | A character vector describing the location of R library trees in which to search for the package, or NULL. The default value of NULL corresponds to all libraries currently known. |
| ...     | additional named arguments such as <code>method</code> and <code>ccaddress</code> to pass to <code>create.post</code> .                                                            |

**Details**

If package is NULL or a base package, this opens the R bugs tracker at <https://bugs.r-project.org/>.

If package is specified, it is assumed that the bug report is about that package, and parts of its 'DESCRIPTION' file are added to the standard information. If the package has a non-empty BugReports field in the 'DESCRIPTION' file specifying the URL of a webpage, that URL will be opened using `browseURL`, otherwise an email directed to the package maintainer will be generated using `create.post`. If there is any other form of BugReports field or a Contact field, this is examined as it may provide a preferred email address.

**Value**

Nothing useful.

### When is there a bug?

If R executes an illegal instruction, or dies with an operating system error message that indicates a problem in the program (as opposed to something like “disk full”), then it is certainly a bug.

Taking forever to complete a command can be a bug, but you must make certain that it was really R’s fault. Some commands simply take a long time. If the input was such that you KNOW it should have been processed quickly, report a bug. If you don’t know whether the command should take a long time, find out by looking in the manual or by asking for assistance.

If a command you are familiar with causes an R error message in a case where its usual definition ought to be reasonable, it is probably a bug. If a command does the wrong thing, that is a bug. But be sure you know for certain what it ought to have done. If you aren’t familiar with the command, or don’t know for certain how the command is supposed to work, then it might actually be working right. Rather than jumping to conclusions, show the problem to someone who knows for certain.

Finally, a command’s intended definition may not be best for statistical analysis. This is a very important sort of problem, but it is also a matter of judgement. Also, it is easy to come to such a conclusion out of ignorance of some of the existing features. It is probably best not to complain about such a problem until you have checked the documentation in the usual ways, feel confident that you understand it, and know for certain that what you want is not available. The mailing list `r-devel@project.org` is a better place for discussions of this sort than the bug list.

If you are not sure what the command is supposed to do after a careful reading of the manual this indicates a bug in the manual. The manual’s job is to make everything clear. It is just as important to report documentation bugs as program bugs.

If the online argument list of a function disagrees with the manual, one of them must be wrong, so report the bug.

### How to report a bug

When you decide that there is a bug, it is important to report it and to report it in a way which is useful. What is most useful is an exact description of what commands you type, from when you start R until the problem happens. Always include the version of R, machine, and operating system that you are using; type version in R to print this. To help us keep track of which bugs have been fixed and which are still open please send a separate report for each bug.

The most important principle in reporting a bug is to report FACTS, not hypotheses or categorizations. It is always easier to report the facts, but people seem to prefer to strain to posit explanations and report them instead. If the explanations are based on guesses about how R is implemented, they will be useless; we will have to try to figure out what the facts must have been to lead to such speculations. Sometimes this is impossible. But in any case, it is unnecessary work for us.

For example, suppose that on a data set which you know to be quite large the command `data.frame(x, y, z, monday, tuesday)` never returns. Do not report that `data.frame()` fails for large data sets. Perhaps it fails when a variable name is a day of the week. If this is so then when we got your report we would try out the `data.frame()` command on a large data set, probably with no day of the week variable name, and not see any problem. There is no way in the world that we could guess that we should try a day of the week variable name.

Or perhaps the command fails because the last command you used was a `[` method that had a bug causing R’s internal data structures to be corrupted and making the `data.frame()` command fail from then on. This is why we need to know what other commands you have typed (or read from your startup file).

It is very useful to try and find simple examples that produce apparently the same bug, and somewhat useful to find simple examples that might be expected to produce the bug but actually do not. If you want to debug the problem and find exactly what caused it, that is wonderful. You should still report the facts as well as any explanations or solutions.

Invoking R with the ‘--vanilla’ option may help in isolating a bug. This ensures that the site profile and saved data files are not read.

A bug report can be generated using the function `bug.report()`. For reports on R this will open the Web page at <https://bugs.r-project.org/>: for a contributed package it will open the package’s bug tracker Web page or help you compose an email to the maintainer.

Bug reports on **contributed packages** should not be sent to the R bug tracker: rather make use of the package argument.

### Author(s)

---

|                |                                                  |
|----------------|--------------------------------------------------|
| capture.output | <i>Send Output to a Character String or File</i> |
|----------------|--------------------------------------------------|

---

### Description

Evaluates its arguments with the output being returned as a character string or sent to a file. Related to [sink](#) similarly to how [with](#) is related to [attach](#).

### Usage

```
capture.output(..., file = NULL, append = FALSE,
               type = c("output", "message"), split = FALSE)
```

### Arguments

|             |                                                                                                                                                                                  |
|-------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ...         | Expressions to be evaluated.                                                                                                                                                     |
| file        | A file name or a <a href="#">connection</a> , or NULL to return the output as a character vector. If the connection is not open, it will be opened initially and closed on exit. |
| append      | logical. If file a file name or unopened connection, append or overwrite?                                                                                                        |
| type, split | are passed to <a href="#">sink()</a> , see there.                                                                                                                                |

### Details

It works via [sink\(<file connection>\)](#) and hence the R code in dots must *not* interfere with the connection (e.g., by calling [closeAllConnections\(\)](#)).

An attempt is made to write output as far as possible to file if there is an error in evaluating the expressions, but for `file = NULL` all output will be lost.

Messages sent to [stderr\(\)](#) (including those from [message](#), [warning](#) and [stop](#)) are captured by `type = "message"`. Note that this can be “unsafe” and should only be used with care.

**Value**

A character string (if file = NULL), or invisible NULL.

**See Also**

[sink](#), [textConnection](#)

**Examples**

```
require(stats)
glmout <- capture.output(summary(glm(case ~ spontaneous+induced,
                                     data = infert, family = binomial()))))

glmout[1:5]
capture.output(1+1, 2+2)
capture.output({1+1; 2+2})

## Not run: ## on Unix-alike with a2ps available
op <- options(useFancyQuotes=FALSE)
pdf <- pipe("a2ps -o - | ps2pdf - tempout.pdf", "w")
capture.output(example(glm), file = pdf)
close(pdf); options(op) ; system("evince tempout.pdf &")

## End(Not run)
```

---

changedFiles

*Detect which Files Have Changed*

---

**Description**

fileSnapshot takes a snapshot of a selection of files, recording summary information about each. changedFiles compares two snapshots, or compares one snapshot to the current state of the file system. The snapshots need not be the same directory; this could be used to compare two directories.

**Usage**

```
fileSnapshot(path = ".", file.info = TRUE, timestamp = NULL,
             md5sum = FALSE, digest = NULL, full.names = length(path) > 1,
             ...)

changedFiles(before, after, path = before$path, timestamp = before$timestamp,
            check.file.info = c("size", "isdir", "mode", "mtime"),
            md5sum = before$md5sum, digest = before$digest,
            full.names = before$full.names, ...)

## S3 method for class 'fileSnapshot'
print(x, verbose = FALSE, ...)

## S3 method for class 'changedFiles'
print(x, verbose = FALSE, ...)
```

**Arguments**

|                 |                                                                                                                                                                                                                           |
|-----------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| path            | character vector; the path(s) to record.                                                                                                                                                                                  |
| file.info       | logical; whether to record <code>file.info</code> values for each file.                                                                                                                                                   |
| timestamp       | character string or NULL; the name of a file to write at the time the snapshot is taken. This gives a quick test for modification, but may be unreliable; see the Details.                                                |
| md5sum          | logical; whether MD5 summaries of each file should be taken as part of the snapshot.                                                                                                                                      |
| digest          | a function or NULL; a function with header <code>function(filename)</code> which will take a vector of filenames and produce a vector of values of the same length, or a matrix with that number of rows.                 |
| full.names      | logical; whether full names (as in <code>list.files</code> ) should be recorded. Must be TRUE if <code>length(path) &gt; 1</code> .                                                                                       |
| ...             | additional parameters to pass to <code>list.files</code> to control the set of files in the snapshots.                                                                                                                    |
| before, after   | objects produced by <code>fileSnapshot</code> ; two snapshots to compare. If after is missing, a new snapshot of the current file system will be produced for comparison, using arguments recorded in before as defaults. |
| check.file.info | character vector; which columns from <code>file.info</code> should be compared.                                                                                                                                           |
| x               | the object to print.                                                                                                                                                                                                      |
| verbose         | logical; whether to list all data when printing.                                                                                                                                                                          |

**Details**

The `fileSnapshot` function uses `list.files` to obtain a list of files, and depending on the `file.info`, `md5sum`, and `digest` arguments, records information about each file.

The `changedFiles` function compares two snapshots.

If the `timestamp` argument to `fileSnapshot` is length 1, a file with that name is created. If it is length 1 in `changedFiles`, the `file_test` function is used to compare the age of all files common to both before and after to it. This test may be unreliable: it compares the current modification time of the after files to the timestamp; that may not be the same as the modification time when the after snapshot was taken. It may also give incorrect results if the clock on the file system holding the timestamp differs from the one holding the snapshot files.

If the `check.file.info` argument contains a non-empty character vector, the indicated columns from the result of a call to `file.info` will be compared.

If `md5sum` is TRUE, `fileSnapshot` will call the `tools::md5sum` function to record the 32 byte MD5 checksum for each file, and `changedFiles` will compare the values. The `digest` argument allows users to provide their own digest function.

**Value**

`fileSnapshot` returns an object of class "fileSnapshot". This is a list containing the fields

|      |                                                                                                      |
|------|------------------------------------------------------------------------------------------------------|
| info | a data frame whose rownames are the filenames, and whose columns contain the requested snapshot data |
| path | the normalized path from the call                                                                    |

timestamp, file.info, md5sum, digest, full.names  
                                   a record of the other arguments from the call

args                              other arguments passed via ... to [list.files](#).

changedFiles produces an object of class "changedFiles". This is a list containing

added, deleted, changed, unchanged  
                                   character vectors of filenames from the before and after snapshots, with obvious meanings

changes                          a logical matrix with a row for each common file, and a column for each comparison test. TRUE indicates a change in that test.

[print](#) methods are defined for each of these types. The [print](#) method for "fileSnapshot" objects displays the arguments used to produce them, while the one for "changedFiles" displays the added, deleted and changed fields if non-empty, and a submatrix of the changes matrix containing all of the TRUE values.

### Author(s)

Duncan Murdoch, using suggestions from Karl Millar and others.

[file.info](#), [file\\_test](#), [md5sum](#).

### Examples

```
# Create some files in a temporary directory
dir <- tempfile()
dir.create(dir)
writeBin(1L, file.path(dir, "file1"))
writeBin(2L, file.path(dir, "file2"))
dir.create(file.path(dir, "dir"))

# Take a snapshot
snapshot <- fileSnapshot(dir, timestamp = tempfile("timestamp"), md5sum=TRUE)

# Change one of the files.
writeBin(3L:4L, file.path(dir, "file2"))

# Display the detected changes. We may or may not see mtime change...
changedFiles(snapshot)
changedFiles(snapshot)$changes
```

---

charClass

*Character Classification*

---

### Description

An interface to the (C99) wide character classification functions in use.

### Usage

```
charClass(x, class)
```

**Arguments**

|                    |                                                                                                                                           |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>     | <b>Either</b> a UTF-8-encoded length-1 character vector <b>or</b> an integer vector of Unicode points (or a vector coercible to integer). |
| <code>class</code> | A character string, one of those given in the ‘Details’ section.                                                                          |

**Details**

The classification into character classes is platform-dependent. The classes are determined by internal tables on Windows and (optionally but by default) on macOS and AIX.

The character classes are interpreted as follows:

"alnum" Alphabetic or numeric.

"alpha" Alphabetic.

"blank" Space or tab.

"cntrl" Control characters.

"digit" Digits 0–9.

"graph" Graphical characters (printable characters except whitespace).

"lower" Lower-case alphabetic.

"print" Printable characters.

"punct" Punctuation characters. Some platforms treat all non-alphanumeric graphical characters as punctuation.

"space" Whitespace, including tabs, form and line feeds and carriage returns. Some OSes include non-breaking spaces, some exclude them.

"upper" Upper-case alphabetic.

"xdigit" Hexadecimal character, one of 0–9A–fa–f.

Alphabetic characters contain all lower- and upper-case ones and some others (for example, those in ‘title case’).

Whether a character is printable is used to decide whether to escape it when printing – see the help for [print.default](#).

If `x` is a character string it should either be ASCII or declared as UTF-8 – see [Encoding](#).

`charClass` was added in R 4.1.0. A less direct way to examine character classes which also worked in earlier versions is to use something like `grepl("[:print:]", intToUtf8(x))` – however, the regular-expression code might not use the same classification functions as printing and on macOS used not to.

**Value**

A logical vector of the length the number of characters or integers in `x`.

**Note**

Non-ASCII digits are excluded by the C99 standard from the class "digit": most platforms will have them as alphabetic.

It is an assumption that the system’s wide character classification functions are coded in Unicode points, but this is known to be true for all recent platforms.

The classification may depend on the locale even on one platform.

**See Also**

Character classes are used in [regular expressions](#).

The OS's man pages for `iswctype` and `wctype`.

**Examples**

```
x <- c(48:70, 32, 0xa0) # Last is non-breaking space
cl <- c("alnum", "alpha", "blank", "digit", "graph", "punct", "upper", "xdigit")
X <- lapply(cl, function(y) charClass(x,y)); names(X) <- cl
X <- as.data.frame(X); row.names(X) <- sQuote(intToUtf8(x, multiple = TRUE))
X

charClass("ABC123", "alpha")
## Some accented capital Greek characters
(x <- "\u0386\u0388\u0389")
charClass(x, "upper")

## How many printable characters are there? (Around 280,000 in Unicode 13.)
## There are 2^21-1 possible Unicode points (most not yet assigned).
pr <- charClass(1:0xffffffff, "print")
table(pr)
```

---

choose.dir

---

*Choose a Folder Interactively on MS Windows*

---

**Description**

Use a Windows shell folder widget to choose a folder interactively.

**Usage**

```
choose.dir(default = "", caption = "Select folder")
```

**Arguments**

|         |                                      |
|---------|--------------------------------------|
| default | which folder to show initially.      |
| caption | the caption on the selection dialog. |

**Details**

This brings up the Windows shell folder selection widget. With the default `default = ""`, 'My Computer' (or similar) is initially selected.

To workaround a bug, on Vista and later only folders under 'Computer' are accessible via the widget.

**Value**

A length-one character vector, character NA if 'Cancel' was selected.

**Note**

This is only available on Windows.

**See Also**

[choose.files](#) (on Windows) and [file.choose](#) (on all platforms).

**Examples**

```
if (interactive() && .Platform$OS.type == "windows")
  choose.dir(getwd(), "Choose a suitable folder")
```

---

choose.files

*Choose a List of Files Interactively on MS Windows*

---

**Description**

Use a Windows file dialog to choose a list of zero or more files interactively.

**Usage**

```
choose.files(default = "", caption = "Select files",
             multi = TRUE, filters = Filters,
             index = nrow(Filters))
```

Filters

**Arguments**

|         |                                                |
|---------|------------------------------------------------|
| default | which filename to show initially               |
| caption | the caption on the file selection dialog       |
| multi   | whether to allow multiple files to be selected |
| filters | a matrix of filename filters (see Details)     |
| index   | which row of filters to use by default         |

**Details**

Unlike [file.choose](#), `choose.files` will always attempt to return a character vector giving a list of files. If the user cancels the dialog, then zero files are returned, whereas [file.choose](#) would signal an error. `choose.dir` chooses a directory.

Windows file dialog boxes include a list of ‘filters’, which allow the file selection to be limited to files of specific types. The `filters` argument to `choose.files` allows the list of filters to be set. It should be an `n` by 2 character matrix. The first column gives, for each filter, the description the user will see, while the second column gives the mask(s) to select those files. If more than one mask is used, separate them by semicolons, with no spaces. The `index` argument chooses which filter will be used initially.

`Filters` is a matrix giving the descriptions and masks for the file types that R knows about. Print it to see typical formats for filter specifications. The examples below show how particular filters may be selected.

If you would like to display files in a particular directory, give a fully qualified file mask (e.g., `"c:\\*.*)" in the default argument. If a directory is not given, the dialog will start in the current directory the first time, and remember the last directory used on subsequent invocations.`

There is a buffer limit on the total length of the selected filenames: it is large but this function is not intended to select thousands of files, when the limit might be reached.

**Value**

A character vector giving zero or more file paths.

**Note**

This is only available on Windows.

**See Also**

[file.choose](#), [choose.dir](#).

[Sys.glob](#) or [list.files](#) to select multiple files by pattern.

**Examples**

```
if (interactive() && .Platform$OS.type == "windows")
  choose.files(filters = Filters[c("zip", "All"),])
```

---

|                  |                                     |
|------------------|-------------------------------------|
| chooseBioCmirror | <i>Select a Bioconductor Mirror</i> |
|------------------|-------------------------------------|

---

**Description**

Interact with the user to choose a Bioconductor mirror.

**Usage**

```
chooseBioCmirror(graphics = getOption("menu.graphics"), ind = NULL,
  local.only = FALSE)
```

**Arguments**

|            |                                                                                                                                                                                                                         |
|------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| graphics   | Logical. If true, use a graphical list: on Windows or the macOS GUI use a list box, and on a Unix-alike use a Tk widget if package <b>tk</b> and an X server are available. Otherwise use a text <a href="#">menu</a> . |
| ind        | Optional numeric value giving which entry to select.                                                                                                                                                                    |
| local.only | Logical, try to get most recent list from the Bioconductor master or use file on local disk only.                                                                                                                       |

**Details**

This sets the [option](#) "BioC\_mirror": it is used before a call to [setRepositories](#). The out-of-the-box default for that option is NULL, which currently corresponds to the mirror <https://bioconductor.org>.

The 'Bioconductor (World-wide)' 'mirror' is a network of mirrors providing reliable world-wide access; other mirrors may provide faster access on a geographically local scale.

ind chooses a row in '[R\\_HOME](#)/doc/BioC\_mirrors.csv', by number.

**Value**

None: this function is invoked for its side effect of updating options("BioC\_mirror").

**See Also**

[setRepositories](#), [chooseCRANmirror](#).

---

|                  |                             |
|------------------|-----------------------------|
| chooseCRANmirror | <i>Select a CRAN Mirror</i> |
|------------------|-----------------------------|

---

**Description**

Interact with the user to choose a CRAN mirror.

**Usage**

```
chooseCRANmirror(graphics = getOption("menu.graphics"), ind = NULL,
                  local.only = FALSE)
```

```
getCRANmirrors(all = FALSE, local.only = FALSE)
```

**Arguments**

|            |                                                                                                                                                                                                                         |
|------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| graphics   | Logical. If true, use a graphical list: on Windows or the macOS GUI use a list box, and on a Unix-alike use a Tk widget if package <b>tk</b> and an X server are available. Otherwise use a text <a href="#">menu</a> . |
| ind        | Optional numeric value giving which entry to select.                                                                                                                                                                    |
| all        | Logical, get all known mirrors or only the ones flagged as OK.                                                                                                                                                          |
| local.only | Logical, try to get most recent list from the CRAN master or use file on local disk only.                                                                                                                               |

**Details**

A list of mirrors is stored in file '[R\\_HOME](#)/doc/CRAN\_mirrors.csv', but first an on-line list of current mirrors is consulted, and the file copy used only if the on-line list is inaccessible.

chooseCRANmirror is called by a Windows GUI menu item and by [contrib.url](#) if it finds the initial dummy value of [options\("repos"\)](#).

HTTPS mirrors with mirroring over ssh will be offered in preference to other mirrors (which are listed in a sub-menu).

ind chooses a row in the list of current mirrors, by number. It is best used with local.only = TRUE and row numbers in '[R\\_HOME](#)/doc/CRAN\_mirrors.csv'.

**Value**

None for chooseCRANmirror(), this function is invoked for its side effect of updating [options\("repos"\)](#).

getCRANmirrors() returns a data frame with mirror information.

**See Also**

[setRepositories](#), [findCRANmirror](#), [chooseBioCmirror](#), [contrib.url](#).

**Description**

How to cite R and R packages in publications.

**Usage**

```
citation(package = "base", lib.loc = NULL, auto = NULL)

readCitationFile(file, meta = NULL)
citHeader(...)
citFooter(...)
```

**Arguments**

|         |                                                                                                                                                                                                                                                                                                       |
|---------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| package | a character string with the name of a single package. An error occurs if more than one package name is given.                                                                                                                                                                                         |
| lib.loc | a character vector with path names of R libraries, or the directory containing the source for package, or NULL. The default value of NULL corresponds to all libraries currently known. If the default is used, the loaded packages are searched before the libraries.                                |
| auto    | a logical indicating whether the default citation auto-generated from the package ‘DESCRIPTION’ metadata should be used or not, or NULL (default), indicating that a ‘CITATION’ file is used if it exists, or an object of class <code>"packageDescription"</code> with package metadata (see below). |
| file    | a file name.                                                                                                                                                                                                                                                                                          |
| meta    | a list of package metadata as obtained by <code>packageDescription</code> , or NULL (the default).                                                                                                                                                                                                    |
| ...     | character strings (which will be <a href="#">pasted</a> ).                                                                                                                                                                                                                                            |

**Details**

The R core development team and the very active community of package authors have invested a lot of time and effort in creating R as it is today. Please give credit where credit is due and cite R and R packages when you use them for data analysis.

Use `citation()` (without arguments) for information on how to cite the base R system in publications.

If `citation()` is called with `package` the name of a non-base package, as controlled by the `auto` argument it either returns the information contained in the package ‘CITATION’ file or auto-generates citation information from the package ‘DESCRIPTION’ file. By default (`auto = NULL`), the ‘CITATION’ file is used if it exists, in which case it is read via `readCitationFile` with `meta` equal to `packageDescription(package, lib.loc)`. One can force auto-generation via `auto = TRUE`.

The auto-generated citation includes URLs for packages installed from the standard repositories CRAN and Bioconductor and from development platforms such as GitHub, GitLab, or R-Forge. In case of CRAN and Bioconductor, DOIs are included as well.

Packages can use an ‘Authors@R’ field in their ‘DESCRIPTION’ to provide (R code giving) a [person](#) object with a refined, machine-readable description of the package “authors” (in particular specifying their precise roles). Only those with an author role will be included in the auto-generated citation.

If the object returned by `citation()` contains only one reference, the associated print method shows both a text version and a BibTeX entry for it. If a package has more than one reference then only the text versions are shown. This threshold is controlled by `options("citation.bibtex.max")`. The BibTeX versions can also be obtained using function `toBibtex()` (see the examples below).

The ‘CITATION’ file of an R package should be placed in the ‘inst’ subdirectory of the package source. The file is an R source file and may contain arbitrary R commands including conditionals and computations. Function `readCitationFile()` is used by `citation()` to extract the information in ‘CITATION’ files. The file is `source()`ed by the R parser in a temporary environment and all resulting bibliographic objects (specifically, inheriting from “[bibentry](#)”) are collected. These are typically produced by one or more `bibentry()` calls, optionally preceded by a `citHeader()` and followed by a `citFooter()` call. One can include an auto-generated package citation in the ‘CITATION’ file via `citation(auto = meta)`.

`readCitationFile` makes use of the Encoding element (if any) of meta to determine the encoding of the file.

## Value

An object of class “citation”, inheriting from class “[bibentry](#)”; see there, notably for the `print` and `format` methods.

`citHeader` and `citFooter` return an empty “[bibentry](#)” storing “outer” header/footer text for the package citation.

## See Also

[bibentry](#)

## Examples

```
## the basic R reference
citation()

## extract the BibTeX entry from the return value
x <- citation()
toBibtex(x)

## references for a package
citation("lattice")
citation("lattice", auto = TRUE) # request the Manual-type reference
citation("foreign")

## a CITATION file with more than one bibentry:
file.show(system.file("CITATION", package="mgcv"))
cm <- citation("mgcv")
cm # header, text references, plus "reminder" about getting BibTeX
print(cm, bibtex = TRUE) # each showing its bibtex code

## a CITATION file including citation(auto = meta)
file.show(system.file("CITATION", package="nlme"))
citation("nlme")
```

cite

*Cite a Bibliography Entry***Description**

Cite a bibentry object in text. The `cite()` function uses the `cite()` function from the default `bibstyle` if present, or `citeNatbib()` if not. `citeNatbib()` uses a style similar to that used by the LaTeX package ‘natbib’.

**Usage**

```

cite(keys, bib, ...)
citeNatbib(keys, bib, textual = FALSE, before = NULL, after = NULL,
            mode = c("authoryear", "numbers", "super"),
            abbreviate = TRUE, longnamesfirst = TRUE,
            bibpunct = c("(", ")", ";", "a", "", ",", previous))

```

**Arguments**

|                             |                                                                                                                                         |
|-----------------------------|-----------------------------------------------------------------------------------------------------------------------------------------|
| <code>keys</code>           | A character vector of keys of entries to cite. May contain multiple keys in a single entry, separated by commas.                        |
| <code>bib</code>            | A " <code>bibentry</code> " object containing the list of documents in which to find the keys.                                          |
| <code>...</code>            | Additional arguments to pass to the <code>cite()</code> function for the default style.                                                 |
| <code>textual</code>        | Produce a “textual” style of citation, i.e. what ‘ <code>\citet</code> ’ would produce in LaTeX.                                        |
| <code>before</code>         | Optional text to display before the citation.                                                                                           |
| <code>after</code>          | Optional text to display after the citation.                                                                                            |
| <code>mode</code>           | The “mode” of citation.                                                                                                                 |
| <code>abbreviate</code>     | Whether to abbreviate long author lists.                                                                                                |
| <code>longnamesfirst</code> | If <code>abbreviate == TRUE</code> , whether to leave the first citation long.                                                          |
| <code>bibpunct</code>       | A vector of punctuation to use in the citation, as used in ‘natbib’. See the Details section.                                           |
| <code>previous</code>       | A list of keys that have been previously cited, to be used when <code>abbreviate == TRUE</code> and <code>longnamesfirst == TRUE</code> |

**Details**

Argument names are chosen based on the documentation for the LaTeX ‘natbib’ package. See that documentation for the interpretation of the `bibpunct` entries.

The entries in `bibpunct` are as follows:

1. The left delimiter.
2. The right delimiter.
3. The separator between references within a citation.
4. An indicator of the “mode”: “n” for numbers, “s” for superscripts, anything else for author-year.

5. Punctuation to go between the author and year.
6. Punctuation to go between years when authorship is suppressed.

Note that if mode is specified, it overrides the mode specification in bibpunct[4]. Partial matching is used for mode.

The defaults for citeNatbib have been chosen to match the JSS style, and by default these are used in cite. See [bibstyle](#) for how to set a different default style.

## Value

A single element character string is returned, containing the citation.

## Author(s)

Duncan Murdoch

## Examples

```
## R reference
rref <- bibentry(
  bibtype = "Manual",
  title = "R: A Language and Environment for Statistical Computing",
  author = person("R Core Team"),
  organization = "R Foundation for Statistical Computing",
  address = "Vienna, Austria",
  year = 2013,
  url = "https://www.R-project.org/",
  key = "R")

## References for boot package and associated book
bref <- c(
  bibentry(
    bibtype = "Manual",
    title = "boot: Bootstrap R (S-PLUS) Functions",
    author = c(
      person("Angelo", "Canty", role = "aut",
        comment = "S original"),
      person(c("Brian", "D."), "Ripley", role = c("aut", "trl", "cre"),
        comment = "R port, author of parallel support",
        email = "ripley@stats.ox.ac.uk")
    ),
    year = "2012",
    note = "R package version 1.3-4",
    url = "https://CRAN.R-project.org/package=boot",
    key = "boot-package"
  ),
  bibentry(
    bibtype = "Book",
    title = "Bootstrap Methods and Their Applications",
    author = as.person("Anthony C. Davison [aut], David V. Hinkley [aut]"),
    year = "1997",
    publisher = "Cambridge University Press",
    address = "Cambridge",
    isbn = "0-521-57391-2",
    url = "http://statwww.epfl.ch/davison/BMA/"
```

```

        key = "boot-book"
      )
    )

    ## Combine and cite
    refs <- c(rref, bref)
    cite("R, boot-package", refs)

    ## Cite numerically
    savestyle <- tools::getBibstyle()
    tools::bibstyle("JSSnumbered", .init = TRUE,
      fmtPrefix = function(paper) paste0("[", paper$.index, "]"),
      cite = function(key, bib, ...)
        citeNatbib(key, bib, mode = "numbers",
          bibpunct = c("[", "]", ";", "n", "", ",", "...")
        )
    cite("R, boot-package", refs, textual = TRUE)
    refs

    ## restore the old style
    tools::bibstyle(savestyle, .default = TRUE)

```

citEntry

*Bibliography Entries (Older Interface)*

## Description

Old interface providing functionality for specifying bibliographic information in enhanced BibTeX style. Since R 2.14.0 this has been superseded by [bibentry](#).

## Usage

```
citEntry(entry, textVersion = NULL, header = NULL, footer = NULL, ...)
```

## Arguments

|             |                                                                                                                                                                                                                                                                               |
|-------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| entry       | a character string with a BibTeX entry type. See section <b>Entry Types</b> in <a href="#">bibentry</a> for details.                                                                                                                                                          |
| textVersion | a character string with a text representation of the reference to optionally be employed for printing.                                                                                                                                                                        |
| header      | a character string with optional header text.                                                                                                                                                                                                                                 |
| footer      | a character string with optional footer text.                                                                                                                                                                                                                                 |
| ...         | for <code>citEntry</code> , arguments of the form <code>tag=value</code> giving the fields of the entry, with <code>tag</code> and <code>value</code> the name and value of the field, respectively. See section <b>Entry Fields</b> in <a href="#">bibentry</a> for details. |

## Value

`citEntry` produces an object of class "bibentry".

**See Also**

[citation](#) for more information about citing R and R packages and ‘CITATION’ files; [bibentry](#) for the newer functionality for representing and manipulating bibliographic information.

---

clipboard

*Read/Write to/from the Clipboard in MS Windows*

---

**Description**

Transfer text between a character vector and the Windows clipboard in MS Windows (only).

**Usage**

```
getClipboardFormats(numeric = FALSE)
readClipboard(format = 13, raw = FALSE)
writeClipboard(str, format = 13)
```

**Arguments**

|         |                                                                                    |
|---------|------------------------------------------------------------------------------------|
| numeric | logical: should the result be in human-readable form (the default) or raw numbers? |
| format  | an integer giving the desired format.                                              |
| raw     | should the value be returned as a raw vector rather than as a character vector?    |
| str     | a character vector or a raw vector.                                                |

**Details**

The Windows clipboard offers data in a number of formats: see e.g. <https://learn.microsoft.com/en-gb/windows/desktop/dataxchg/clipboard-formats>.

The standard formats include

|                 |    |                                      |
|-----------------|----|--------------------------------------|
| CF_TEXT         | 1  | Text in the machine's locale         |
| CF_BITMAP       | 2  |                                      |
| CF_METAFILEPICT | 3  | Metafile picture                     |
| CF_SYLK         | 4  | Symbolic link                        |
| CF_DIF          | 5  | Data Interchange Format              |
| CF_TIFF         | 6  | Tagged-Image File Format             |
| CF_OEMTEXT      | 7  | Text in the OEM codepage             |
| CF_DIB          | 8  | Device-Independent Bitmap            |
| CF_PALETTE      | 9  |                                      |
| CF_PENDATA      | 10 |                                      |
| CF_RIFF         | 11 | Audio data                           |
| CF_WAVE         | 12 | Audio data                           |
| CF_UNICODETEXT  | 13 | Text in Unicode (UCS-2)              |
| CF_ENHMETAFILE  | 14 | Enhanced metafile                    |
| CF_HDROP        | 15 | Drag-and-drop data                   |
| CF_LOCALE       | 16 | Locale for the text on the clipboard |
| CF_MAX          | 17 | Shell-oriented formats               |

Applications normally make data available in one or more of these and possibly additional private formats. Use `raw = TRUE` to read binary formats, `raw = FALSE` (the default) for text formats. The current codepage is used to convert text to Unicode text, and information on that is contained in the `CF_LOCALE` format. (Take care if you are running R in a different locale from Windows. It is recommended to read as Unicode text, so that Windows does the conversion based on `CF_LOCALE`, if available.)

The `writeClipboard` function will write a character vector as text or Unicode text with standard CRLF line terminators. It will copy a raw vector directly to the clipboard without any changes. It is recommended to use Unicode text (the default) instead of text to avoid interoperability problems. (Note that R 4.2 and newer on recent systems uses UTF-8 as the native encoding but the machine's locale uses a different encoding.)

### Value

For `getClipboardFormats`, a character or integer vector of available formats, in numeric order. If non human-readable character representation is known, the number is returned.

For `readClipboard`, a character vector by default, a raw vector if `raw` is `TRUE`, or `NULL`, if the format is unavailable.

For `writeClipboard` an invisible logical indicating success or failure.

### Note

This is only available on Windows.

### See Also

[file](#) which can be used to set up a connection to a clipboard.

---

close.socket

*Close a Socket*

---

### Description

Closes the socket and frees the space in the file descriptor table. The port may not be freed immediately.

### Usage

```
close.socket(socket, ...)
```

### Arguments

|        |                                                    |
|--------|----------------------------------------------------|
| socket | a socket object                                    |
| ...    | further arguments passed to or from other methods. |

### Value

logical indicating success or failure

### Author(s)

Thomas Lumley

**See Also**

[make.socket](#), [read.socket](#)

Compiling in support for sockets was optional prior to R 3.3.0: see [capabilities](#)("sockets") to see if it is available.

combn

*Generate All Combinations of n Elements, Taken m at a Time***Description**

Generate all combinations of the elements of `x` taken `m` at a time. If `x` is a positive integer, returns all combinations of the elements of `seq(x)` taken `m` at a time. If argument `FUN` is not `NULL`, applies a function given by the argument to each point. If `simplify` is `FALSE`, returns a list; otherwise returns an [array](#), typically a [matrix](#). ... are passed unchanged to the `FUN` function, if specified.

**Usage**

```
combn(x, m, FUN = NULL, simplify = TRUE, ...)
```

**Arguments**

|                       |                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|-----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>        | vector source for combinations, or integer <code>n</code> for <code>x &lt;- seq_len(n)</code> .                                                                                                                                                                                                                                                                                                                                                    |
| <code>m</code>        | number of elements to choose.                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <code>FUN</code>      | function to be applied to each combination; default <code>NULL</code> means the identity, i.e., to return the combination (vector of length <code>m</code> ).                                                                                                                                                                                                                                                                                      |
| <code>simplify</code> | logical indicating if the result should be simplified to an <a href="#">array</a> (typically a <a href="#">matrix</a> ); if <code>FALSE</code> , the function returns a <a href="#">list</a> . Note that when <code>simplify = TRUE</code> as by default, the dimension of the result is simply determined from <code>FUN(1st combination)</code> (for efficiency reasons). This will badly fail if <code>FUN(u)</code> is not of constant length. |
| ...                   | optionally, further arguments to <code>FUN</code> .                                                                                                                                                                                                                                                                                                                                                                                                |

**Details**

Factors `x` are accepted.

**Value**

A [list](#) or [array](#), see the `simplify` argument above. In the latter case, the identity `dim(combn(n, m)) == c(m, choose(n, m))` holds.

**Author(s)**

Scott Chasalow wrote the original in 1994 for S; R package **combinat** and documentation by Vince Carey <stvjc@channing.harvard.edu>; small changes by the R core team, notably to return an array in all cases of `simplify = TRUE`, e.g., for `combn(5, 5)`.

**References**

Nijenhuis, A. and Wilf, H.S. (1978) *Combinatorial Algorithms for Computers and Calculators*; Academic Press, NY.

**See Also**

[choose](#) for fast computation of the *number* of combinations. [expand.grid](#) for creating a data frame from all combinations of factors or vectors.

**Examples**

```
combn(letters[1:4], 2)
(m <- combn(10, 5, min)) # minimum value in each combination
mm <- combn(15, 6, function(x) matrix(x, 2, 3))
stopifnot(round(choose(10, 5)) == length(m), is.array(m), # 1-dimensional
           c(2,3, round(choose(15, 6))) == dim(mm))

## Different way of encoding points:
combn(c(1,1,1,1,2,2,2,3,3,4), 3, tabulate, nbins = 4)

## Compute support points and (scaled) probabilities for a
## Multivariate-Hypergeometric(n = 3, N = c(4,3,2,1)) p.f.:
# table.mat(t(combn(c(1,1,1,1,2,2,2,3,3,4), 3, tabulate, nbins = 4)))

## Assuring the identity
for(n in 1:7)
  for(m in 0:n) stopifnot(is.array(cc <- combn(n, m)),
                        dim(cc) == c(m, choose(n, m)),
                        identical(cc, combn(n, m, identity)) || m == 1)
```

compareVersion

*Compare Two Package Version Numbers***Description**

Compare two package version numbers to see which is later.

**Usage**

```
compareVersion(a, b)
```

**Arguments**

a, b                      Character strings representing package version numbers.

**Details**

R package version numbers are of the form x.y-z for integers x, y and z, with components after x optionally missing (in which case the version number is older than those with the components present).

**Value**

0 if the numbers are equal, -1 if b is later and 1 if a is later (analogous to the C function strcmp).

Gives an R error on malformed inputs.

**See Also**

[package\\_version](#), [library](#), [packageStatus](#).

**Examples**

```
compareVersion("1.0", "1.0-1")
compareVersion("7.2-0", "7.1-12")
```

---

**COMPILE***Compile Files for Use with R on Unix-alikes*

---

**Description**

Compile given source files so that they can subsequently be collected into a shared object using R CMD SHLIB or an executable program using R CMD LINK. Not available on Windows.

**Usage**

```
R CMD COMPILE [options] srcfiles
```

**Arguments**

|          |                                                                                                                                                                                                                                                                                                                                                                                                    |
|----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| srcfiles | A list of the names of source files to be compiled. Currently, C, C++, Objective C, Objective C++ and Fortran are supported; the corresponding files should have the extensions <code>‘.c’</code> , <code>‘.cc’</code> (or <code>‘.cpp’</code> ), <code>‘.m’</code> , <code>‘.mm’</code> (or <code>‘.M’</code> ), <code>‘.f’</code> and <code>‘.f90’</code> or <code>‘.f95’</code> , respectively. |
| options  | A list of compile-relevant settings, or for obtaining information about usage and version of the utility.                                                                                                                                                                                                                                                                                          |

**Details**

R CMD SHLIB can both compile and link files into a shared object: since it knows what run-time libraries are needed when passed C++, Fortran and Objective C(++) sources, passing source files to R CMD SHLIB is more reliable.

Objective C and Objective C++ support is optional and will work only if the corresponding compilers were available at R configure time: their main usage is on macOS.

Compilation arranges to include the paths to the R public C/C++ headers.

As this compiles code suitable for incorporation into a shared object, it generates PIC code: that might occasionally be undesirable for the main code of an executable program.

This is a make-based facility, so will not compile a source file if a newer corresponding `‘.o’` file is present.

**Note**

Some binary distributions of R have COMPILE in a separate bundle, e.g. an R-devel RPM.

This is not available on Windows.

---

contrib.url

*Find Appropriate Paths in CRAN-like Repositories*

---

**Description**

contrib.url adds the appropriate type-specific path within a repository to each URL in repos.

**Usage**

```
contrib.url(repos, type = getOption("pkgType"))
```

**Arguments**

|       |                                                                                             |
|-------|---------------------------------------------------------------------------------------------|
| repos | character vector, the base URL(s) of the repositories to use.                               |
| type  | character string, indicating which type of packages: see <a href="#">install.packages</a> . |

**Details**

If type = "both" this will use the source repository.

**Value**

A character vector of the same length as repos.

**See Also**

[setRepositories](#) to set [options\("repos"\)](#), the most common value used for argument repos. [available.packages](#), [download.packages](#), [install.packages](#).

The ‘R Installation and Administration’ manual for how to set up a repository.

---

count.fields

*Count the Number of Fields per Line*

---

**Description**

count.fields counts the number of fields, as separated by sep, in each of the lines of file read.

**Usage**

```
count.fields(file, sep = "", quote = "\"\"", skip = 0,
             blank.lines.skip = TRUE, comment.char = "#")
```

## Arguments

|                               |                                                                                                                                                                      |
|-------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>file</code>             | a character string naming an ASCII data file, or a <a href="#">connection</a> , which will be opened if necessary, and if so closed at the end of the function call. |
| <code>sep</code>              | the field separator character. Values on each line of the file are separated by this character. By default, arbitrary amounts of whitespace can separate fields.     |
| <code>quote</code>            | the set of quoting characters                                                                                                                                        |
| <code>skip</code>             | the number of lines of the data file to skip before beginning to read data.                                                                                          |
| <code>blank.lines.skip</code> | logical: if TRUE blank lines in the input are ignored.                                                                                                               |
| <code>comment.char</code>     | character: a character vector of length one containing a single character or an empty string.                                                                        |

## Details

This used to be used by [read.table](#) and can still be useful in discovering problems in reading a file by that function.

For the handling of comments, see [scan](#).

Consistent with [scan](#), `count.fields` allows quoted strings to contain newline characters. In such a case the starting line will have the field count recorded as NA, and the ending line will include the count of all fields from the beginning of the record.

## Value

A vector with the numbers of fields found.

## See Also

[read.table](#)

## Examples

```
fil <- tempfile()
cat("NAME", "1:John", "2:Paul", file = fil, sep = "\n")
count.fields(fil, sep = ":")
unlink(fil)
```

---

create.post

*Ancillary Function for Preparing Emails and Postings*

---

## Description

An ancillary function used by [bug.report](#) and [help.request](#) to prepare emails for submission to package maintainers or to R mailing lists.

## Usage

```
create.post(instructions = character(), description = "post",
            subject = "",
            method = getOption("mailer"),
            address = "the relevant mailing list",
            ccaddress = getOption("ccaddress", ""),
            filename = "R.post", info = character())
```

**Arguments**

|              |                                                                                                                                                                                   |
|--------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| instructions | Character vector of instructions to put at the top of the template email.                                                                                                         |
| description  | Character string: a description to be incorporated into messages.                                                                                                                 |
| subject      | Subject of the email. Optional except for the "mailx" method.                                                                                                                     |
| method       | Submission method, one of "none", "mailto", "gnudoit", "ess" or (Unix only) "mailx". See 'Details'.                                                                               |
| address      | Recipient's email address, where applicable: for package bug reports sent by email this defaults to the address of the package maintainer (the first if more than one is listed). |
| ccaddress    | Optional email address for copies with the "mailx" and "mailto" methods. Use ccaddress = "" for no copy.                                                                          |
| filename     | Filename to use for setting up the email (or storing it when method is "none" or sending mail fails).                                                                             |
| info         | character vector of information to include in the template email below the 'please do not edit the information below' line.                                                       |

**Details**

What this does depends on the method. The function first creates a template email body.

**none** A file editor (see [file.edit](#)) is opened with instructions and the template email. When this returns, the completed email is in file `file` ready to be read/pasted into an email program.

**mailto** This opens the default email program with a template email (including address, Cc: address and subject) for you to edit and send.

This works where default mailers are set up (usual on macOS and Windows, and where `xdg-open` is available and configured on other Unix-alikes: if that fails it tries the browser set by `R_BROWSER`).

This is the 'factory-fresh' default method.

**mailx** (Unix-alikes only.) A file editor (see [file.edit](#)) is opened with instructions and the template email. When this returns, it is mailed using a Unix command line mail utility such as `mailx`, to the address (and optionally, the Cc: address) given.

**gnudoit** An (X)emacs mail buffer is opened for the email to be edited and sent: this requires the `gnudoit` program to be available. Currently subject is ignored.

**ess** The body of the template email is sent to `stdout`.

**Value**

Invisible `NULL`.

**See Also**

[bug.report](#), [help.request](#).

data

*Data Sets***Description**

Loads specified data sets, or list the available data sets.

**Usage**

```
data(..., list = character(), package = NULL, lib.loc = NULL,
      verbose = getOption("verbose"), envir = .GlobalEnv,
      overwrite = TRUE)
```

**Arguments**

|                        |                                                                                                                                                                                                                  |
|------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>...</code>       | literal character strings or names.                                                                                                                                                                              |
| <code>list</code>      | a character vector.                                                                                                                                                                                              |
| <code>package</code>   | a character vector giving the package(s) to look in for data sets, or NULL.<br>By default, all packages in the search path are used, then the ‘data’ subdirectory (if present) of the current working directory. |
| <code>lib.loc</code>   | a character vector of directory names of R libraries, or NULL. The default value of NULL corresponds to all libraries currently known.                                                                           |
| <code>verbose</code>   | a logical. If TRUE, additional diagnostics are printed.                                                                                                                                                          |
| <code>envir</code>     | the <a href="#">environment</a> where the data should be loaded.                                                                                                                                                 |
| <code>overwrite</code> | logical: should existing objects of the same name in <code>envir</code> be replaced?                                                                                                                             |

**Details**

Currently, four formats of data files are supported:

1. files ending ‘.R’ or ‘.r’ are [source\(\)](#)d in, with the R working directory changed temporarily to the directory containing the respective file. (data ensures that the **utils** package is attached, in case it had been run *via* `utils::data`.)
2. files ending ‘.RData’ or ‘.rdata’ or ‘.rda’ are [load\(\)](#)ed.
3. files ending ‘.tab’, ‘.txt’ or ‘.TXT’ are read using [read.table\(\)](#) (`header = TRUE`, `as.is=FALSE`), and hence result in a data frame.
4. files ending ‘.csv’ or ‘.CSV’ are read using [read.table\(\)](#) (`header = TRUE`, `sep = ";"`, `as.is=FALSE`), and also result in a data frame.

If more than one matching file name is found, the first on this list is used. (Files with extensions ‘.txt’, ‘.tab’ or ‘.csv’ can be compressed, with or without further extension ‘.gz’, ‘.bz2’ or ‘.xz’.)

The data sets to be loaded can be specified as a set of character strings or names, or as the character vector `list`, or as both.

For each given data set, the first two types (‘.R’ or ‘.r’, and ‘.RData’ or ‘.rda’ files) can create several variables in the load environment, which might all be named differently from the data set. The third and fourth types will always result in the creation of a single variable with the same name (without extension) as the data set.

If no data sets are specified, `data` lists the available data sets. For each package, it looks for a data index in the ‘Meta’ subdirectory or, if this is not found, scans the ‘data’ subdirectory for data files using `list_files_with_type`. The information about available data sets is returned in an object of class “packageIQR”. The structure of this class is experimental. Where the datasets have a different name from the argument that should be used to retrieve them the index will have an entry like `beaver1` (beavers) which tells us that dataset `beaver1` can be retrieved by the call `data(beavers)`.

If `lib.loc` and `package` are both `NULL` (the default), the data sets are searched for in all the currently loaded packages then in the ‘data’ directory (if any) of the current working directory.

If `lib.loc = NULL` but `package` is specified as a character vector, the specified package(s) are searched for first amongst loaded packages and then in the default libraries (see `.libPaths`).

If `lib.loc` is specified (and not `NULL`), packages are searched for in the specified libraries, even if they are already loaded from another library.

To just look in the ‘data’ directory of the current working directory, set `package = character(0)` (and `lib.loc = NULL`, the default).

## Value

A character vector of all data sets specified (whether found or not), or information about all available data sets in an object of class “packageIQR” if none were specified.

## Good practice

There is no requirement for `data(foo)` to create an object named `foo` (nor to create one object), although it much reduces confusion if this convention is followed (and it is enforced if datasets are lazy-loaded).

`data()` was originally intended to allow users to load datasets from packages for use in their examples, and as such it loaded the datasets into the workspace `.GlobalEnv`. This avoided having large datasets in memory when not in use: that need has been almost entirely superseded by lazy-loading of datasets.

The ability to specify a dataset by name (without quotes) is a convenience: in programming the datasets should be specified by character strings (with quotes).

Use of `data` within a function without an `envir` argument has the almost always undesirable side-effect of putting an object in the user’s workspace (and indeed, of replacing any object of that name already there). It would almost always be better to put the object in the current evaluation environment by `data(..., envir = environment())`. However, two alternatives are usually preferable, both described in the ‘Writing R Extensions’ manual.

- For sets of data, set up a package to use lazy-loading of data.
- For objects which are system data, for example lookup tables used in calculations within the function, use a file ‘R/sysdata.rda’ in the package sources or create the objects by R code at package installation time.

A sometimes important distinction is that the second approach places objects in the namespace but the first does not. So if it is important that the function sees `mytable` as an object from the package, it is system data and the second approach should be used. In the unusual case that a package uses a lazy-loaded dataset as a default argument to a function, that needs to be specified by `::`, e.g., `survival::survexp.us`.

**Warning**

This function creates objects in the `envir` environment (by default the user's workspace) replacing any which already existed. `data("foo")` can silently create objects other than `foo`: there have been instances in published packages where it created/replaced `.Random.seed` and hence change the seed for the session.

**Note**

One can take advantage of the search order and the fact that a `‘.R’` file will change directory. If raw data are stored in `‘mydata.txt’` then one can set up `‘mydata.R’` to read `‘mydata.txt’` and pre-process it, e.g., using `transform()`. For instance one can convert numeric vectors to factors with the appropriate labels. Thus, the `‘.R’` file can effectively contain a metadata specification for the plaintext formats.

**See Also**

[help](#) for obtaining documentation on data sets, [save](#) for *creating* the second (`‘.rda’`) kind of data, typically the most efficient one.

The ‘Writing R Extensions’ manual for considerations in preparing the `‘data’` directory of a package.

**Examples**

```
require(utils)
data()                      # list all available data sets
try(data(package = "rpart"), silent = TRUE) # list the data sets in the rpart package
data(USArrests, "VADeaths") # load the data sets 'USArrests' and 'VADeaths'
## Not run: ## Alternatively
ds <- c("USArrests", "VADeaths"); data(list = ds)
## End(Not run)
help(USArrests)             # give information on data set 'USArrests'
```

---

dataentry

---

*Spreadsheet Interface for Entering Data*

---

**Description**

A spreadsheet-like editor for entering or editing data.

**Usage**

```
data.entry(..., Modes = NULL, Names = NULL)
dataentry(data, modes)
de(..., Modes = list(), Names = NULL)
```

**Arguments**

|                    |                                                                                                              |
|--------------------|--------------------------------------------------------------------------------------------------------------|
| <code>...</code>   | A list of variables: currently these should be numeric or character vectors or list containing such vectors. |
| <code>Modes</code> | The modes to be used for the variables.                                                                      |
| <code>Names</code> | The names to be used for the variables.                                                                      |

|                    |                                                                                                                               |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------|
| <code>data</code>  | A list of numeric and/or character vectors.                                                                                   |
| <code>modes</code> | A list of length up to that of <code>data</code> giving the modes of (some of) the variables. <code>list()</code> is allowed. |

## Details

The data entry editor is only available on some platforms and GUIs. Where available it provides a means to visually edit a matrix or a collection of variables (including a data frame) as described in the Notes section.

`data.entry` has side effects, any changes made in the spreadsheet are reflected in the variables. Function `de` and the internal functions `de.ncols`, `de.setup` and `de.restore` are designed to help achieve these side effects. If the user passes in a matrix, `X` say, then the matrix is broken into columns before `dataentry` is called. Then on return the columns are collected and glued back together and the result assigned to the variable `X`. If you don't want this behaviour use `dataentry` directly.

The primitive function is `dataentry`. It takes a list of vectors of possibly different lengths and modes (the second argument) and opens a spreadsheet with these variables being the columns. The columns of the data entry window are returned as vectors in a list when the spreadsheet is closed.

`de.ncols` counts the number of columns which are supplied as arguments to `data.entry`. It attempts to count columns in lists, matrices and vectors. `de.setup` sets things up so that on return the columns can be regrouped and reassigned to the correct name. This is handled by `de.restore`.

## Value

`de` and `dataentry` return the edited value of their arguments. `data.entry` invisibly returns a vector of variable names but its main value is its side effect of assigning new version of those variables in the user's workspace.

## Resources

The data entry window responds to `X` resources of class `R_dataentry`. Resources `foreground`, `background` and `geometry` are utilized.

## Note

The details of interface to the data grid may differ by platform and GUI. The following description applies to the X11-based implementation under Unix.

You can navigate around the grid using the cursor keys or by clicking with the (left) mouse button on any cell. The active cell is highlighted by thickening the surrounding rectangle. Moving to the right or down will scroll the grid as needed: there is no constraint to the rows or columns currently in use.

There are alternative ways to navigate using the keys. Return and (keypad) Enter and LineFeed all move down. Tab moves right and Shift-Tab move left. Home moves to the top left.

PageDown or Control-F moves down a page, and PageUp or Control-B up by a page. End will show the last used column and the last few rows used (in any column).

Using any other key starts an editing process on the currently selected cell: moving away from that cell enters the edited value whereas Esc cancels the edit and restores the previous value. When the editing process starts the cell is cleared. In numerical columns (the default) only letters making up a valid number (including `- . eE`) are accepted, and entering an invalid edited value (such as blank) enters NA in that cell. The last entered value can be deleted using the BackSpace or Del(ete) key. Only a limited number of characters (currently 29) can be entered in a cell, and if necessary only

the start or end of the string will be displayed, with the omissions indicated by > or <. (The start is shown except when editing.)

Entering a value in a cell further down a column than the last used cell extends the variable and fills the gap (if any) by NAs (not shown on screen).

The column names can only be selected by clicking in them. This gives a popup menu to select the column type (currently Real (numeric) or Character) or to change the name. Changing the type converts the current contents of the column (and converting from Character to Real may generate NAs.) If changing the name is selected the header cell becomes editable (and is cleared). As with all cells, the value is entered by moving away from the cell by clicking elsewhere or by any of the keys for moving down (only).

New columns are created by entering values in them (and not by just assigning a new name). The mode of the column is auto-detected from the first value entered: if this is a valid number it gives a numeric column. Unused columns are ignored, so adding data in var5 to a three-column grid adds one extra variable, not two.

The Copy button copies the currently selected cell: paste copies the last copied value to the current cell, and right-clicking selects a cell *and* copies in the value. Initially the value is blank, and attempts to paste a blank value will have no effect.

Control-L will refresh the display, recalculating field widths to fit the current entries.

In the default mode the column widths are chosen to fit the contents of each column, with a default of 10 characters for empty columns. you can specify fixed column widths by setting option `de.cellwidth` to the required fixed width (in characters). (set it to zero to return to variable widths). The displayed width of any field is limited to 600 pixels (and by the window width).

[vi](#), [edit](#): edit uses `dataentry` to edit data frames.

## Examples

```
# call data entry with variables x and y
## Not run: data.entry(x, y)
```

---

debugcall

*Debug a Call*

---

## Description

Set or unset debugging flags based on a call to a function. Takes into account S3/S4 method dispatch based on the classes of the arguments in the call.

## Usage

```
debugcall(call, once = FALSE)
undebugcall(call)
```

## Arguments

|                   |                                                                                                         |
|-------------------|---------------------------------------------------------------------------------------------------------|
| <code>call</code> | An R expression calling a function. The called function will be debugged. See <a href="#">Details</a> . |
| <code>once</code> | logical; if TRUE, debugging only occurs once, as via <code>debugonce</code> . Defaults to FALSE         |

**Details**

`debugcall` debugs the non-generic function, S3 method or S4 method that would be called by evaluating `call`. Thus, the user does not need to specify the signature when debugging methods. Although the call is actually to the generic, it is the method that is debugged, not the generic, except for non-standard S3 generics (see [isS3stdGeneric](#)).

**Value**

`debugcall` invisibly returns the debugged call expression.

**Note**

Non-standard evaluation is used to retrieve the call (via [substitute](#)). For this reason, passing a variable containing a call expression, rather than the call expression itself, will not work.

**See Also**

[debug](#) for the primary debugging interface

**Examples**

```
## Not run:
## Evaluate call after setting debugging
##
f <- factor(1:10)
res <- eval(debugcall(summary(f)))

## End(Not run)
```

---

debugger

*Post-Mortem Debugging*

---

**Description**

Functions to dump the evaluation environments (frames) and to examine dumped frames.

**Usage**

```
dump.frames(dumpto = "last.dump", to.file = FALSE,
            include.GlobalEnv = FALSE)
debugger(dump = last.dump)

limitedLabels(value, maxwidth = getOption("width") - 5L)
```

**Arguments**

|                                |                                                                                                                                                                                                              |
|--------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>dumpto</code>            | a character string. The name of the object or file to dump to.                                                                                                                                               |
| <code>to.file</code>           | logical. Should the dump be to an R object or to a file?                                                                                                                                                     |
| <code>include.GlobalEnv</code> | logical indicating if a <i>copy</i> of the <a href="#">.GlobalEnv</a> environment should be included in addition to the <a href="#">sys.frames()</a> . Will be particularly useful when used in a batch job. |

|          |                                                                                                                                          |
|----------|------------------------------------------------------------------------------------------------------------------------------------------|
| dump     | an R dump object created by <code>dump.frames</code> .                                                                                   |
| value    | a <a href="#">list</a> of <a href="#">calls</a> to be formatted, e.g., for user menus.                                                   |
| maxwidth | optional length to which to trim the result of <code>limitedLabels()</code> ; values smaller than 40 or larger than 1000 are winsorized. |

## Details

To use post-mortem debugging, set the option `error` to be a call to `dump.frames`. By default this dumps to an R object `last.dump` in the workspace, but it can be set to dump to a file (a dump of the object produced by a call to [save](#)). The dumped object contains the call stack, the active environments and the last error message as returned by [geterrmessage](#).

When dumping to file, `dump.to` gives the name of the dumped object and the file name has `‘.rda’` appended.

A dump object of class `"dump.frames"` can be examined by calling `debugger`. This will give the error message and a list of environments from which to select repeatedly. When an environment is selected, it is copied and the [browser](#) called from within the copy. Note that not all the information in the original frame will be available, e.g. promises which have not yet been evaluated and the contents of any `...` argument.

If `dump.frames` is installed as the error handler, execution will continue even in non-interactive sessions. See the examples for how to dump and then quit.

`limitedLabels(v)` takes a [list](#) of calls whose elements may have a `srcref` attribute and returns a vector that pastes a formatted version of those attributes onto the formatted version of the elements, all finally [strtrim\(\)](#)med to `maxwidth`.

## Value

Invisible NULL.

## Note

Functions such as [sys.parent](#) and [environment](#) applied to closures will not work correctly inside `debugger`.

If the error occurred when computing the default value of a formal argument the debugger will report “recursive default argument reference” when trying to examine that environment.

Of course post-mortem debugging will not work if R is too damaged to produce and save the dump, for example if it has run out of workspace.

demo

*Demonstrations of R Functionality***Description**

demo is a user-friendly interface to running some demonstration R scripts. demo() gives the list of available topics.

**Usage**

```
demo(topic, package = NULL, lib.loc = NULL,
```

```
character.only = FALSE, verbose = getOption("verbose"),
type = c("console", "html"), echo = TRUE,
ask = getOption("demo.ask"),
encoding = getOption("encoding"))
```

## Arguments

|                |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| topic          | the topic which should be demonstrated, given as a <a href="#">name</a> or literal character string, or a character string, depending on whether <code>character.only</code> is <code>FALSE</code> (default) or <code>TRUE</code> . If omitted, the list of available topics is displayed.                                                                                                                                                                                                                                                                       |
| package        | a character vector giving the packages to look into for demos, or <code>NULL</code> . By default, all packages in the search path are used.                                                                                                                                                                                                                                                                                                                                                                                                                      |
| lib.loc        | a character vector of directory names of R libraries, or <code>NULL</code> . The default value of <code>NULL</code> corresponds to all libraries currently known. If the default is used, the loaded packages are searched before the libraries.                                                                                                                                                                                                                                                                                                                 |
| character.only | logical; if <code>TRUE</code> , use <code>topic</code> as character string.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| verbose        | a logical. If <code>TRUE</code> , additional diagnostics are printed.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| type           | character: whether to show output in the console or a browser (using the dynamic help system). The latter is honored only in interactive sessions and if the <a href="#">knitr</a> package is installed. Several other arguments are silently ignored in that case, including <code>lib.loc</code> .                                                                                                                                                                                                                                                             |
| echo           | a logical. If <code>TRUE</code> , show the R input when sourcing.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| ask            | a logical (or "default") indicating if <a href="#">devAskNewPage</a> ( <code>ask = TRUE</code> ) should be called before graphical output happens from the demo code. The value "default" (the factory-fresh default) means to ask if <code>echo == TRUE</code> and the graphics device appears to be interactive. This parameter applies both to any currently opened device and to any devices opened by the demo code. If this is evaluated to <code>TRUE</code> and the session is <a href="#">interactive</a> , the user is asked to press RETURN to start. |
| encoding       | See <a href="#">source</a> . If the package has a declared encoding, that takes preference.                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

## Details

If no topics are given, `demo` lists the available demos. For `type = "console"`, the corresponding information is returned in an object of class "packageIQR".

## See Also

[source](#) and [devAskNewPage](#) which are called by `demo`. [example](#) to run code in the Examples section of help pages.

## Examples

```
demo() # for attached packages

## All available demos:
demo(package = .packages(all.available = TRUE))

## Display a demo, pausing between pages
demo(lm.glm, package = "stats", ask = TRUE)
```

```
## Display it without pausing
demo(lm.glm, package = "stats", ask = FALSE)

## Not run:
ch <- "scoping"
demo(ch, character = TRUE)

## End(Not run)

## Find the location of a demo
system.file("demo", "lm.glm.R", package = "stats")
```

---

DLL.version

*DLL Version Information on MS Windows*

---

## Description

On MS Windows only, return the version of the package and the version of R used to build the DLL, if available.

## Usage

```
DLL.version(path)
```

## Arguments

path                      character vector of length one giving the complete path to the DLL.

## Value

If the DLL does not exist, NULL.

A character vector of length two, giving the DLL version and the version of R used to build the DLL. If the information is not available, the corresponding string is empty.

## Note

This is only available on Windows.

## Examples

```
if(.Platform$OS.type == "windows") withAutoprint({
  DLL.version(file.path(R.home("bin"), "R.dll"))
  DLL.version(file.path(R.home(), "library/stats/libs", .Platform$r_arch, "stats.dll"))
})
```

download.file

*Download File from the Internet***Description**

This function can be used to download a file from the Internet.

**Usage**

```
download.file(url, destfile, method, quiet = FALSE, mode = "w",
             cacheOK = TRUE,
             extra = getOption("download.file.extra"),
             headers = NULL, ...)
```

**Arguments**

|          |                                                                                                                                                                                                                                                                                                           |
|----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| url      | a <a href="#">character</a> string (or longer vector for the "libcurl" method) naming the URL of a resource to be downloaded.                                                                                                                                                                             |
| destfile | a character string (or vector, see the url argument) with the file path where the downloaded file is to be saved. Tilde-expansion is performed.                                                                                                                                                           |
| method   | Method to be used for downloading files. Current download methods are "internal", "libcurl", "wget", "curl" and "wininet" (Windows only), and there is a value "auto": see 'Details' and 'Note'.<br>The method can also be set through the option "download.file.method": see <a href="#">options()</a> . |
| quiet    | If TRUE, suppress status messages (if any), and the progress bar.                                                                                                                                                                                                                                         |
| mode     | character. The mode with which to write the file. Useful values are "w", "wb" (binary), "a" (append) and "ab". Not used for methods "wget" and "curl". See also 'Details', notably about using "wb" for Windows.                                                                                          |
| cacheOK  | logical. Is a server-side cached value acceptable?                                                                                                                                                                                                                                                        |
| extra    | character vector of additional command-line arguments for the "wget" and "curl" methods.                                                                                                                                                                                                                  |
| headers  | named character vector of additional HTTP headers to use in HTTP[S] requests. It is ignored for non-HTTP[S] URLs. The User-Agent header taken from the HTTPUserAgent option (see <a href="#">options</a> ) is automatically used as the first header.                                                     |
| ...      | allow additional arguments to be passed, unused.                                                                                                                                                                                                                                                          |

**Details**

The function `download.file` can be used to download a single file as described by `url` from the internet and store it in `destfile`.

The `url` must start with a scheme such as 'http://', 'https://' or 'file://'. Which methods support which schemes varies by R version, but `method = "auto"` will try to find a method which supports the scheme.

For `method = "auto"` (the default) currently the "internal" method is used for 'file://' URLs and "libcurl" for all others.

Support for method "libcurl" was optional on Windows prior to R 4.2.0: use `capabilities("libcurl")` to see if it is supported on an earlier version. It uses an external library of that name (<https://curl.se/libcurl/>) against which R can be compiled.

When method "libcurl" is used, there is support for simultaneous downloads, so `url` and `destfile` can be character vectors of the same length greater than one (but the method has to be specified explicitly and not *via* "auto"). For a single URL and `quiet = FALSE` a progress bar is shown in interactive use.

Nowadays the "internal" method only supports the 'file://' scheme (for which it is the default). On Windows the "wininet" method currently supports 'file://' and (but deprecated with a warning) 'http://' and 'https://' schemes.

For methods "wget" and "curl" a system call is made to the tool given by method, and the respective program must be installed on your system and be in the search path for executables. They will block all other activity on the R process until they complete: this may make a GUI unresponsive.

`cacheOK = FALSE` is useful for 'http://' and 'https://' URLs: it will attempt to get a copy directly from the site rather than from an intermediate cache. It is used by [available.packages](#).

The "libcurl" and "wget" methods follow 'http://' and 'https://' redirections to any scheme they support. (For method "curl" use argument `extra = "-L"`. To disable redirection in wget, use `extra = "--max-redirect=0"`.) The "wininet" method supports some redirections but not all. (For method "libcurl", messages will quote the endpoint of redirections.)

See [url](#) for how 'file://' URLs are interpreted, especially on Windows. The "internal" and "wininet" methods do not percent-decode, but the "libcurl" and "curl" methods do: method "wget" does not support them.

Most methods do not percent-encode special characters such as spaces in URLs (see [URLencode](#)), but it seems the "wininet" method does.

The remaining details apply to the "wininet" and "libcurl" methods only.

The timeout for many parts of the transfer can be set by the option `timeout` which defaults to 60 seconds. This is often insufficient for downloads of large files (50MB or more) and so should be increased when `download.file` is used in packages to do so. Note that the user can set the default timeout by the environment variable `R_DEFAULT_INTERNET_TIMEOUT` in recent versions of R, so to ensure that this is not decreased packages should use something like

```
options(timeout = max(300, getOption("timeout")))
```

(It is unrealistic to require download times of less than 1s/MB.)

A HTTP[S] URL may require authentication. One may specify a username and password as part of the URL, i.e. "https://username:password@machine/...". This is not recommended with HTTP as the credentials will be sent in plaintext. With HTTPS, they will be encrypted, but still may appear in plaintext e.g. in server logs. Alternatively, the credentials may be specified via Authorization in argument headers, but that is more involved for the user and wouldn't allow simultaneous download from different URLs requiring authentication. With "libcurl", it is possible to have the credentials in a netrc file which can be specified by the option `netrc` and the default may be set by the environment variable `R_DEFAULT_NETRC`. The file should not be readable by other users. See <https://everything.curl.dev/usingcurl/netrc.html> for further details.

The level of detail provided during transfer can be set by the `quiet` argument and the `internet.info` option: the details depend on the platform and scheme. For the "libcurl" method values of the option less than 2 give verbose output.

A progress bar tracks the transfer platform-specifically:

**On Windows** If the file length is known, the full width of the bar is the known length. Otherwise the initial width represents 100 Kbytes and is doubled whenever the current width is exceeded. (In non-interactive use this uses a text version. If the file length is known, an equals sign represents 2% of the transfer completed; otherwise a dot represents 10Kb.)

**On a Unix-alike** If the file length is known, an equals sign represents 2% of the transfer completed; otherwise a dot represents 10Kb.

The choice of binary transfer (mode = "wb" or "ab") is important on Windows, since unlike Unix-alikes it does distinguish between text and binary files and for text transfers changes '\n' line endings to '\r\n' (aka 'CRLF').

On Windows, if mode is not supplied (`missing()`) and url ends in one of '.gz', '.bz2', '.xz', '.tgz', '.zip', '.jar', '.rda', '.rds', '.RData' or '.pdf', mode = "wb" is set so that a binary transfer is done to help unwary users.

Code written to download binary files must use mode = "wb" (or "ab"), but the problems incurred by a text transfer will only be seen on Windows.

## Value

An (invisible) integer code, 0 for success and non-zero for failure. For the "wget" and "curl" methods this is the status code returned by the external program. The "internal" method can return 1, but will in most cases throw an error. When simultaneously downloading two or more files (see the url argument) and download of at least one file succeeds, 0 is returned with attribute `retvals`, which provides an integer vector of the same length as url with a result code for each file (0 for success and non-zero for failure).

What happens to the destination file(s) in the case of error depends on the method and R version. Currently the "internal", "wininet" and "libcurl" methods will remove the file if the URL is unavailable except when mode specifies appending when the file should be unchanged.

## Setting Proxies

For the Windows-only method "wininet", the 'Internet Options' of the system are used to choose proxies and so on; these are set in the Control Panel and are those used for system browsers.

For the "libcurl" and "curl" methods, proxies can be set *via* the environment variables `http_proxy` or `ftp_proxy`. See <https://curl.se/libcurl/c/libcurl-tutorial.html> for further details.

## Secure URLs

Methods which access 'https://' and (where supported) 'ftps://' URLs should try to verify the site certificates. This is usually done using the CA root certificates installed by the OS (although we have seen instances in which these got removed rather than updated). For further information see <https://curl.se/docs/sslcerts.html>.

On Windows with method = "libcurl", the CA root certificates are provided by the OS when R was linked with libcurl with Schannel enabled, which is the current default in Rtools. This can be verified by checking that `libcurlVersion()` returns a version string containing "Schannel". If it does not, for verification to be on the environment variable `CURL_CA_BUNDLE` must be set to a path to a certificate bundle file, usually named 'ca-bundle.crt' or 'curl-ca-bundle.crt'. (This is normally done automatically for a binary installation of R, which installs '`R_HOME/etc/curl-ca-bundle.crt`' and sets `CURL_CA_BUNDLE` to point to it if that environment variable is not already set.) For an updated certificate bundle, see <https://curl.se/docs/sslcerts.html>. Currently one can download a copy

from <https://raw.githubusercontent.com/bagder/ca-bundle/master/ca-bundle.crt> and set `CURL_CA_BUNDLE` to the full path to the downloaded file.

On Windows with `method = "libcurl"`, when R was linked with `libcurl` with `Schannel` enabled, the connection fails if it cannot be established that the certificate has not been revoked. Some MITM proxies present particularly in corporate environments do not work with this behavior. It can be changed by setting environment variable `R_LIBCURL_SSL_REVOKE_BEST_EFFORT` to `TRUE`, with the consequence of reducing security.

Note that the root certificates used by R may or may not be the same as used in a browser, and indeed different browsers may use different certificate bundles (there is typically a build option to choose either their own or the system ones).

### Good practice

Setting the method should be left to the end user. Neither of the `wget` nor `curl` commands is widely available: you can check if one is available *via* [Sys.which](#), and should do so in a package or script.

If you use `download.file` in a package or script, you must check the return value, since it is possible that the download will fail with a non-zero status but not an R error.

The supported methods do change: method `libcurl` was introduced in R 3.2.0 and was optional on Windows until R 4.2.0 – use [capabilities\("libcurl"\)](#) in a program to see if it is available.

### 'ftp://' URLs

Most modern browsers do not support such URLs, and 'https://' ones are much preferred for use in R. 'ftps://' URLs have always been rare, and are nowadays even less supported.

It is intended that R will continue to allow such URLs for as long as `libcurl` does, but as they become rarer this is increasingly untested. What 'protocols' the version of `libcurl` being used supports can be seen by calling [libcurlVersion\(\)](#).

These URLs are accessed using the FTP protocol which has a number of variants. One distinction is between 'active' and '(extended) passive' modes: which is used is chosen by the client. The "libcurl" method uses passive mode which was almost universally used by browsers before they dropped support altogether.

### Note

Files of more than 2GB are supported on 64-bit builds of R; they may be truncated on some 32-bit builds.

Methods "wget" and "curl" are mainly for historical compatibility but provide may provide capabilities not supported by the "libcurl" or "wininet" methods.

Method "wget" can be used with proxy firewalls which require user/password authentication if proper values are stored in the configuration file for wget.

wget (<https://www.gnu.org/software/wget/>) is commonly installed on Unix-alikes (but not macOS). Windows binaries are available from MSYS2 and elsewhere.

curl (<https://curl.se/>) is installed on macOS and increasingly commonly on Unix-alikes. Windows binaries are available at that URL.

|-------------------|------------------------------------------------------|
| download.packages | <i>Download Packages from CRAN-like Repositories</i> |
|-------------------|------------------------------------------------------|

---

## Description

These functions can be used to automatically compare the version numbers of installed packages with the newest available version on the repositories and update outdated packages on the fly.

## Usage

```
download.packages(pkgs, destdir, available = NULL,
                  repos = getOption("repos"),
                  contriburl = contrib.url(repos, type),
                  method, type = getOption("pkgType"), ...)
```

## Arguments

|            |                                                                                                                                                                                                            |
|------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| pkgs       | character vector of the names of packages whose latest available versions should be downloaded from the repositories.                                                                                      |
| destdir    | directory where downloaded packages are to be stored.                                                                                                                                                      |
| available  | an object as returned by <a href="#">available.packages</a> listing packages available at the repositories, or NULL which makes an internal call to <a href="#">available.packages</a> .                   |
| repos      | character vector, the base URL(s) of the repositories to use, i.e., the URL of the CRAN master such as "https://cran.r-project.org" or ones of its mirrors, "https://cloud.r-project.org".                 |
| contriburl | URL(s) of the contrib sections of the repositories. Use this argument only if your repository mirror is incomplete, e.g., because you burned only the 'contrib' section on a CD. Overrides argument repos. |
| method     | Download method, see <a href="#">download.file</a> .                                                                                                                                                       |
| type       | character string, indicate which type of packages: see <a href="#">install.packages</a> and 'Details'.                                                                                                     |
| ...        | additional arguments to be passed to <a href="#">download.file</a> and <a href="#">available.packages</a> .                                                                                                |

## Details

`download.packages` takes a list of package names and a destination directory, downloads the newest versions and saves them in `destdir`. If the list of available packages is not given as argument, it is obtained from repositories. If a repository is local, i.e. the URL starts with "file:", then the packages are not downloaded but used directly. Both "file:" and "file:/" are allowed as prefixes to a file path. Use the latter only for URLs: see [url](#) for their interpretation. (Other forms of 'file:/' URLs are not supported.)

For `download.packages`, `type = "both"` looks at source packages only.

**Value**

A two-column matrix of names and destination file names of those packages successfully downloaded. If packages are not available or there is a problem with the download, suitable warnings are given.

**See Also**

[available.packages](#), [contrib.url](#).

The main use is by [install.packages](#).

See [download.file](#) for how to handle proxies and other options to monitor file transfers.

edit

*Invoke a Text Editor*

---

**Description**

Invoke a text editor on an R object.

**Usage**

```
edit(name, ...)
## Default S3 method:
edit(name = NULL, file = "", title = NULL,
      editor = getOption("editor"), ...)

vi(name = NULL, file = "")
emacs(name = NULL, file = "")
pico(name = NULL, file = "")
xemacs(name = NULL, file = "")
xedit(name = NULL, file = "")
```

**Arguments**

|        |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|--------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| name   | a named object that you want to edit. For the default method, if name is missing then the file specified by file is opened for editing.                                                                                                                                                                                                                                                                                                                                                                                                                         |
| file   | a string naming the file to write the edited version to.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| title  | a display name for the object being edited.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| editor | usually a character string naming (or giving the path to) the text editor you want to use. On Unix the default is set from the environment variables EDITOR or VISUAL if either is set, otherwise vi is used. On Windows it defaults to "internal", the script editor. On the macOS GUI the argument is ignored and the document editor is always used.<br><br>editor can also be an R function, in which case it is called with the arguments name, file, and title. Note that such a function will need to independently implement all desired functionality. |
| ...    | further arguments to be passed to or from methods.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

## Details

edit invokes the text editor specified by editor with the object name to be edited. It is a generic function, currently with a default method and one for data frames and matrices.

data.entry can be used to edit data, and is used by edit to edit matrices and data frames on systems for which data.entry is available.

It is important to realize that edit does not change the object called name. Instead, a copy of name is made and it is that copy which is changed. Should you want the changes to apply to the object name you must assign the result of edit to name. (Try [fix](#) if you want to make permanent changes to an object.)

In the form edit(name), edit deparses name into a temporary file and invokes the editor editor on this file. Quitting from the editor causes file to be parsed and that value returned. Should an error occur in parsing, possibly due to incorrect syntax, no value is returned. Calling edit(), with no arguments, will result in the temporary file being reopened for further editing.

Note that deparsing is not perfect, and the object recreated after editing can differ in subtle ways from that deparsed: see [dput](#) and [.deparseOpts](#). (The deparse options used are the same as the defaults for dump.) Editing a function will preserve its environment. See [edit.data.frame](#) for further changes that can occur when editing a data frame or matrix.

Currently only the internal editor in Windows makes use of the title option; it displays the given name in the window header.

## Note

The functions vi, emacs, pico, xemacs, xedit rely on the corresponding editor being available and being on the path. This is system-dependent.

[edit.data.frame](#), [data.entry](#), [fix](#).

## Examples

```
## Not run:
# use xedit on the function mean and assign the changes
mean <- edit(mean, editor = "xedit")

# use vi on mean and write the result to file mean.out
vi(mean, file = "mean.out")

## End(Not run)
```

---

edit.data.frame

*Edit Data Frames and Matrices*

---

## Description

Use data editor on data frame or matrix contents.

## Usage

```
## S3 method for class 'data.frame'
edit(name, factor.mode = c("character", "numeric"),
      edit.row.names = any(row.names(name) != 1:nrow(name)), ...)

## S3 method for class 'matrix'
edit(name, edit.row.names = !is.null(dn[[1]]), ...)
```

## Arguments

|                             |                                                                                                                                                         |
|-----------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>name</code>           | A data frame or (numeric, logical or character) matrix.                                                                                                 |
| <code>factor.mode</code>    | How to handle factors (as integers or using character levels) in a data frame. Can be abbreviated.                                                      |
| <code>edit.row.names</code> | logical. Show the row names (if they exist) be displayed as a separate editable column? It is an error to ask for this on a matrix with NULL row names. |
| <code>...</code>            | further arguments passed to or from other methods.                                                                                                      |

## Details

At present, this only works on simple data frames containing numeric, logical or character vectors and factors, and numeric, logical or character matrices. Any other mode of matrix will give an error, and a warning is given when the matrix has a class (which will be discarded).

Data frame columns are coerced on input to *character* unless numeric (in the sense of `is.numeric`), logical or factor. A warning is given when classes are discarded. Special characters (tabs, non-printing ASCII, etc.) will be displayed as escape sequences.

Factors columns are represented in the spreadsheet as either numeric vectors (which are more suitable for data entry) or character vectors (better for browsing). After editing, vectors are padded with NA to have the same length and factor attributes are restored. The set of factor levels can not be changed by editing in numeric mode; invalid levels are changed to NA and a warning is issued. If new factor levels are introduced in character mode, they are added at the end of the list of levels in the order in which they encountered.

It is possible to use the data-editor's facilities to select the mode of columns to swap between numerical and factor columns in a data frame. Changing any column in a numerical matrix to character will cause the result to be coerced to a character matrix. Changing the mode of logical columns is not supported.

For a data frame, the row names will be taken from the original object if `edit.row.names = FALSE` and the number of rows is unchanged, and from the edited output if `edit.row.names = TRUE` and there are no duplicates. (If the row.names column is incomplete, it is extended by entries like row223.) In all other cases the row names are replaced by `seq(length = nrow)`.

For a matrix, colnames will be added (of the form col7) if needed. The rownames will be taken from the original object if `edit.row.names = FALSE` and the number of rows is unchanged (otherwise NULL), and from the edited output if `edit.row.names = TRUE`. (If the row.names column is incomplete, it is extended by entries like row223.)

Editing a matrix or data frame will lose all attributes apart from the row and column names.

## Value

The edited data frame or matrix.

**Note**

`fix(dataframe)` works for in-place editing by calling this function.

If the data editor is not available, a dump of the object is presented for editing using the default method of `edit`.

At present the data editor is limited to 65535 rows.

example

*Run an Examples Section from the Online Help*

---

**Description**

Run all the **R** code from the **Examples** part of **R**'s online help topic, with possible exceptions due to `\dontrun`, `\dontshow`, and `\donttest` tags, see 'Details' below.

**Usage**

```
example(topic, package = NULL, lib.loc = NULL,
        character.only = FALSE, give.lines = FALSE, local = FALSE,
        type = c("console", "html"), echo = TRUE,
        verbose = getOption("verbose"),
        setRNG = FALSE, ask = getOption("example.ask"),
        prompt.prefix = abbreviate(topic, 6),
        catch.aborts = FALSE,
        run.dontrun = FALSE, run.donttest = interactive())
```

**Arguments**

|                      |                                                                                                                                                                                                                                                         |
|----------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>topic</code>   | name or literal character string: the online <a href="#">help</a> topic the examples of which should be run.                                                                                                                                            |
| <code>package</code> | a character vector giving the package names to look into for the topic, or <code>NULL</code> (the default), when all packages on the <a href="#">search</a> path are used.                                                                              |
| <code>lib.loc</code> | a character vector of directory names of <b>R</b> libraries, or <code>NULL</code> . The default value of <code>NULL</code> corresponds to all libraries currently known. If the default is used, the loaded packages are searched before the libraries. |

|                             |                                                                                                                                                                                                                                                                                                                                                                                                                               |
|-----------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>character.only</code> | a logical indicating whether topic can be assumed to be a character string.                                                                                                                                                                                                                                                                                                                                                   |
| <code>give.lines</code>     | logical: if true, the <i>lines</i> of the example source code are returned as a character vector.                                                                                                                                                                                                                                                                                                                             |
| <code>local</code>          | logical: if TRUE evaluate locally, if FALSE evaluate in the workspace.                                                                                                                                                                                                                                                                                                                                                        |
| <code>type</code>           | character: whether to show output in the console or a browser (using the dynamic help system). The latter is honored only in interactive sessions and if the <a href="#">knitr</a> package is installed. Several other arguments are silently ignored in that case, including <code>setRNG</code> and <code>lib.loc</code> .                                                                                                  |
| <code>echo</code>           | logical; if TRUE, show the R input when sourcing.                                                                                                                                                                                                                                                                                                                                                                             |
| <code>verbose</code>        | logical; if TRUE, show even more when running example code.                                                                                                                                                                                                                                                                                                                                                                   |
| <code>setRNG</code>         | logical or expression; if not FALSE, the random number generator state is saved, then initialized to a specified state, the example is run and the (saved) state is restored. <code>setRNG = TRUE</code> sets the same state as R CMD <a href="#">check</a> does for running a package's examples. This is currently equivalent to <code>setRNG = {RNGkind("default", "default", "default"); set.seed(1)}</code> .            |
| <code>ask</code>            | logical (or "default") indicating if <a href="#">devAskNewPage</a> ( <code>ask = TRUE</code> ) should be called before graphical output happens from the example code. The value "default" (the factory-fresh default) means to ask if <code>echo</code> is true and the graphics device appears to be interactive. This parameter applies both to any currently opened device and to any devices opened by the example code. |
| <code>prompt.prefix</code>  | character; prefixes the prompt to be used if <code>echo</code> is true (as it is by default).                                                                                                                                                                                                                                                                                                                                 |
| <code>catch.aborts</code>   | logical, passed on to <a href="#">source()</a> , indicating that "abort"ing errors should be caught.                                                                                                                                                                                                                                                                                                                          |
| <code>run.dontrun</code>    | logical indicating that <code>\dontrun</code> should be ignored, i.e., do run the enclosed code.                                                                                                                                                                                                                                                                                                                              |
| <code>run.donttest</code>   | logical indicating that <code>\donttest</code> should be ignored, i.e., do run the enclosed code.                                                                                                                                                                                                                                                                                                                             |

## Details

If `lib.loc` is not specified, the packages are searched for amongst those already loaded, then in the libraries given by [.libPaths\(\)](#). If `lib.loc` is specified, packages are searched for only in the specified libraries, even if they are already loaded from another library. The search stops at the first package found that has help on the topic.

An attempt is made to load the package before running the examples, but this will not replace a package loaded from another location.

If `local = TRUE` objects are not created in the workspace and so not available for examination after example completes: on the other hand they cannot overwrite objects of the same name in the workspace.

As detailed in the 'Writing R Extensions' manual, the author of the help page can tag parts of the examples with the following exception rules:

`\dontrun` encloses code that should not be run.

`\dontshow` encloses code that is invisible on help pages, but will be run both by the package checking tools, and the `example()` function. This was previously `\testonly`, and that form is still accepted.

`\donttest` encloses code that typically should be run, but not during package checking. The default `run.donttest = interactive\(\)` leads `example()` use in other help page examples to skip `\donttest` sections appropriately.

The additional `\dontdiff` tag (in  $R \geq 4.4.0$ ) produces special comments in the code run by `example` (for `Rdiff`-based testing of example output), but does not affect which code is run or displayed on the help page.

### Value

The value of the last evaluated expression, unless `give.lines` is true, where a `character` vector is returned.

### Author(s)

Martin Maechler and others

### See Also

[demo](#)

### Examples

```
example(InsectSprays)
## force use of the standard package 'stats':
example("smooth", package = "stats", lib.loc = .Library)

## set RNG *before* example as when R CMD check is run:

r1 <- example(quantile, setRNG = TRUE)
x1 <- rnorm(1)
u <- runif(1)
## identical random numbers
r2 <- example(quantile, setRNG = TRUE)
x2 <- rnorm(1)
stopifnot(identical(r1, r2))
## but x1 and x2 differ since the RNG state from before example()
## differs and is restored!
x1; x2

## Exploring examples code:
## How large are the examples of "lm..." functions?
lmex <- sapply(apropos("^lm", mode = "function"),
               example, character.only = TRUE, give.lines = TRUE)
lengths(lmex)
```

---

file.edit

*Edit One or More Files*

---

### Description

Edit one or more files in a text editor.

### Usage

```
file.edit(..., title = file, editor = getOption("editor"),
           fileEncoding = "")
```

**Arguments**

|              |                                                                                                                                                      |
|--------------|------------------------------------------------------------------------------------------------------------------------------------------------------|
| ...          | one or more character vectors containing the names of the files to be displayed. These will be tilde-expanded: see <a href="#">path.expand</a> .     |
| title        | the title to use in the editor; defaults to the filename.                                                                                            |
| editor       | the text editor to be used, usually as a character string naming (or giving the path to) the text editor you want to use See ‘Details’.              |
| fileEncoding | the encoding to assume for the file: the default is to assume the native encoding. See the ‘Encoding’ section of the help for <a href="#">file</a> . |

**Details**

The behaviour of this function is very system-dependent. Currently files can be opened only one at a time on Unix; on Windows, the internal editor allows multiple files to be opened, but has a limit of 50 simultaneous edit windows.

The title argument is used for the window caption in Windows, and is currently ignored on other platforms.

Any error in re-encoding the files to the native encoding will cause the function to fail.

The default for editor is system-dependent. On Windows it defaults to "internal", the script editor, and in the macOS GUI the document editor is used whatever the value of editor. On Unix the default is set from the environment variables EDITOR or VISUAL if either is set, otherwise vi is used.

editor can also be an R function, in which case it is called with the arguments name, file, and title. Note that such a function will need to independently implement all desired functionality.

On Windows, UTF-8-encoded paths not valid in the current locale can be used.

**Examples**

```
## Not run:
# open two R scripts for editing
file.edit("script1.R", "script2.R")

## End(Not run)
```

---

file\_test

---

*Shell-style Tests on Files*

---

**Description**

Utility for shell-style file tests.

**Usage**

```
file_test(op, x, y)
```

**Arguments**

|      |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| op   | a character string specifying the test to be performed. Unary tests (only x is used) are "-f" (existence and not being a directory), "-d" (existence and directory), "-L" or "-h" (existence and symbolic link), "-x" (executable as a file or searchable as a directory), "-w" (writable) and "-r" (readable). Binary tests are "-nt" (strictly newer than, using the modification dates) and "-ot" (strictly older than): in both cases the test is false unless both files exist. |
| x, y | character vectors giving file paths.                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

**Details**

'Existence' here means being on the file system and accessible by the stat system call (or a 64-bit extension) – on a Unix-alike this requires execute permission on all of the directories in the path that leads to the file, but no permissions on the file itself.

For the meaning of "-x" on Windows see [file.access](#).

**See Also**

[file.exists](#) which only tests for existence (test -e on some systems) but not for not being a directory.

[file.path](#), [file.info](#)

**Examples**

```
dir <- file.path(R.home(), "library", "stats")
file_test("-d", dir)
file_test("-nt", file.path(dir, "R"), file.path(dir, "demo"))
```

---

findCRANmirror

*Find CRAN Mirror Preference*

---

**Description**

Find out if a CRAN mirror has been selected for the current session.

**Usage**

```
findCRANmirror(type = c("src", "web"))
```

**Arguments**

|      |                                                                  |
|------|------------------------------------------------------------------|
| type | Is the mirror to be used for package sources or web information? |
|------|------------------------------------------------------------------|

**Details**

Find out if a CRAN mirror has been selected for the current session. If so, return its URL else return "https://CRAN.R-project.org".

The mirror is looked for in several places.

- The value of the environment variable R\_CRAN\_SRC or R\_CRAN\_WEB (depending on type), if set.

- An entry in `getOption("repos")` named 'CRAN' which is not the default '"@CRAN@"'.
- The 'CRAN' URL entry in the 'repositories' file (see [setRepositories](#)), if it is not the default '"@CRAN@"'.

The two types allow for partial local CRAN mirrors, for example those mirroring only the package sources where `getOption("repos")` might point to the partial mirror and `R_CRAN_WEB` point to a full (remote) mirror.

### Value

A character string.

### See Also

[setRepositories](#), [chooseCRANmirror](#)

### Examples

```
c(findCRANmirror("src"), findCRANmirror("web"))

Sys.setenv(R_CRAN_WEB = "https://cloud.r-project.org")
c(findCRANmirror("src"), findCRANmirror("web"))
```

---

findLineNum

*Find the Location of a Line of Source Code, or Set a Breakpoint There*

---

### Description

These functions locate objects containing particular lines of source code, using the information saved when the code was parsed with `keep.source = TRUE`.

### Usage

```
findLineNum(srcfile, line, nameonly = TRUE,
            envir = parent.frame(), lastenv)

setBreakpoint(srcfile, line, nameonly = TRUE,
              envir = parent.frame(), lastenv, verbose = TRUE,
              tracer, print = FALSE, clear = FALSE, ...)
```

### Arguments

|                       |                                                                                                          |
|-----------------------|----------------------------------------------------------------------------------------------------------|
| <code>srcfile</code>  | The name of the file containing the source code.                                                         |
| <code>line</code>     | The line number within the file. See Details for an alternate way to specify this.                       |
| <code>nameonly</code> | If TRUE (the default), we require only a match to <code>basename(srcfile)</code> , not to the full path. |
| <code>envir</code>    | Where do we start looking for function objects?                                                          |
| <code>lastenv</code>  | Where do we stop? See the Details.                                                                       |
| <code>verbose</code>  | Should we print information on where breakpoints were set?                                               |

|        |                                                                                                                           |
|--------|---------------------------------------------------------------------------------------------------------------------------|
| tracer | An optional tracer function to pass to <a href="#">trace</a> . By default, a call to <a href="#">browser</a> is inserted. |
| print  | The print argument to pass to <a href="#">trace</a> .                                                                     |
| clear  | If TRUE, call <a href="#">untrace</a> rather than <a href="#">trace</a> .                                                 |
| ...    | Additional arguments to pass to <a href="#">trace</a> .                                                                   |

## Details

The findLineNum function searches through all objects in environment `envir`, its parent, grandparent, etc., all the way back to `lastenv`.

`lastenv` defaults to the global environment if `envir` is not specified, and to the root environment `emptyenv()` if `envir` is specified. (The first default tends to be quite fast, and will usually find all user code other than S4 methods; the second one is quite slow, as it will typically search all attached system libraries.)

For convenience, `envir` may be specified indirectly: if it is not an environment, it will be replaced with `environment(envir)`.

`setBreakpoint` is a simple wrapper function for [trace](#) and [untrace](#). It will set or clear breakpoints at the locations found by `findLineNum`.

The `srcfile` is normally a filename entered as a character string, but it may be a "`srcfile`" object, or it may include a suffix like "`filename.R#nn`", in which case the number `nn` will be used as a default value for `line`.

As described in the description of the `where` argument on the man page for [trace](#), the R package system uses a complicated scheme that may include more than one copy of a function in a package. The user will typically see the public one on the search path, while code in the package will see a private one in the package namespace. If you set `envir` to the environment of a function in the package, by default `findLineNum` will find both versions, and `setBreakpoint` will set the breakpoint in both. (This can be controlled using `lastenv`; e.g., `envir = environment(foo)`, `lastenv = globalenv()` will find only the private copy, as the search is stopped before seeing the public copy.)

S version 4 methods are also somewhat tricky to find. They are stored with the generic function, which may be in the **base** or other package, so it is usually necessary to have `lastenv = emptyenv()` in order to find them. In some cases transformations are done by R when storing them and `findLineNum` may not be able to find the original code. Many special cases, e.g. methods on primitive generics, are not yet supported.

## Value

`findLineNum` returns a list of objects containing location information. A print method is defined for them.

`setBreakpoint` has no useful return value; it is called for the side effect of calling [trace](#) or [untrace](#).

**Examples**

```
## Not run:
# Find what function was defined in the file mysource.R at line 100:
findLineNum("mysource.R#100")

# Set a breakpoint in both copies of that function, assuming one is in the
# same namespace as myfunction and the other is on the search path
setBreakpoint("mysource.R#100", envir = myfunction)

## End(Not run)
```

fix

*Fix an Object***Description**

fix invokes [edit](#) on x and then assigns the new (edited) version of x in the user's workspace.

**Usage**

```
fix(x, ...)
```

**Arguments**

x                    the name of an R object, as a name or a character string.  
 ...                  arguments to pass to editor: see [edit](#).

**Details**

The name supplied as x need not exist as an R object, in which case a function with no arguments and an empty body is supplied for editing.

Editing an R object may change it in ways other than are obvious: see the comment under [edit](#). See [edit.data.frame](#) for changes that can occur when editing a data frame or matrix.

**See Also**

[edit](#), [edit.data.frame](#)

**Examples**

```
## Not run:
## Assume 'my.fun' is a user defined function :
fix(my.fun)
## now my.fun is changed
## Also,
fix(my.data.frame) # calls up data editor
fix(my.data.frame, factor.mode="char") # use of ...

## End(Not run)
```

---

|               |                                  |
|---------------|----------------------------------|
| flush.console | <i>Flush Output to a Console</i> |
|---------------|----------------------------------|

---

**Description**

This does nothing except on console-based versions of R. On the macOS and Windows GUIs, it ensures that the display of output in the console is current, even if output buffering is on.

**Usage**

```
flush.console()
```

---

|        |                                           |
|--------|-------------------------------------------|
| format | <i>Format Unordered and Ordered Lists</i> |
|--------|-------------------------------------------|

---

**Description**

Format unordered (itemize) and ordered (enumerate) lists.

**Usage**

```
formatUL(x, label = "*", offset = 0,
         width = 0.9 * getOption("width"))
formatOL(x, type = "arabic", offset = 0, start = 1,
         width = 0.9 * getOption("width"))
```

**Arguments**

|        |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|--------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| x      | a character vector of list items.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| label  | a character string used for labelling the items.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| offset | a non-negative integer giving the offset (indentation) of the list.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| width  | a positive integer giving the target column for wrapping lines in the output.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| type   | a character string specifying the ‘type’ of the labels in the ordered list. If "arabic" (default), arabic numerals are used. For "Alph" or "alph", single upper or lower case letters are employed (in this case, the number of the last item must not exceed 26). Finally, for "Roman" or "roman", the labels are given as upper or lower case roman numerals (with the number of the last item maximally 3999). type can be given as a unique abbreviation of the above, or as one of the HTML style tokens "1" (arabic), "A"/"a" (alphabetic), or "I"/"i" (roman), respectively. |
| start  | a positive integer specifying the starting number of the first item in an ordered list.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

**Value**

A character vector with the formatted entries.

**See Also**

[formatDL](#) for formatting description lists.

**Examples**

```
## A simpler recipe.
x <- c("Mix dry ingredients thoroughly.",
      "Pour in wet ingredients.",
      "Mix for 10 minutes.",
      "Bake for one hour at 300 degrees.")
## Format and output as an unordered list.
writeLines(formatUL(x))
## Format and output as an ordered list.
writeLines(formatOL(x))
## Ordered list using lower case roman numerals.
writeLines(formatOL(x, type = "i"))
## Ordered list using upper case letters and some offset.
writeLines(formatOL(x, type = "A", offset = 5))
```

---

getAnywhere

*Retrieve an R Object, Including from a Namespace*

---

**Description**

These functions locate all objects with name matching their argument, whether visible on the search path, registered as an S3 method or in a namespace but not exported. `getAnywhere()` returns the objects and `argsAnywhere()` returns the arguments of any objects that are functions.

**Usage**

```
getAnywhere(x)
argsAnywhere(x)
```

**Arguments**

x                      a character string or name.

**Details**

These functions look at all loaded namespaces, whether or not they are associated with a package on the search list.

They do not search literally “anywhere”: for example, local evaluation frames and namespaces that are not loaded will not be searched.

Where functions are found as registered S3 methods, an attempt is made to find which namespace registered them. This may not be correct, especially if namespaces have been unloaded.

**Value**

For `getAnywhere()` an object of class "getAnywhere". This is a list with components

|                      |                                                              |
|----------------------|--------------------------------------------------------------|
| <code>name</code>    | the name searched for                                        |
| <code>objs</code>    | a list of objects found                                      |
| <code>where</code>   | a character vector explaining where the object(s) were found |
| <code>visible</code> | logical: is the object visible                               |
| <code>dups</code>    | logical: is the object identical to one earlier in the list. |

In computing whether objects are identical, their environments are ignored.

Normally the structure will be hidden by the `print` method. There is a `[` method to extract one or more of the objects found.

For `argsAnywhere()` one or more argument lists as returned by [args](#).

**See Also**

[getS3method](#) to find the method which would be used: this might not be the one of those returned by `getAnywhere` since it might have come from a namespace which was unloaded or be registered under another name.

[get](#), [getFromNamespace](#), [args](#)

**Examples**

```
getAnywhere("format.dist")
getAnywhere("simpleLoess") # not exported from stats
argsAnywhere(format.dist)
```

---

|                               |                                                    |
|-------------------------------|----------------------------------------------------|
| <code>getFromNamespace</code> | <i>Utility Functions for Developing Namespaces</i> |
|-------------------------------|----------------------------------------------------|

---

**Description**

Utility functions to access and replace the non-exported functions in a namespace, for use in developing packages with namespaces.

They should not be used in production code (except perhaps `assignInMyNamespace`, but see the 'Note').

**Usage**

```
getFromNamespace(x, ns, pos = -1, envir = as.environment(pos))

assignInNamespace(x, value, ns, pos = -1,
                  envir = as.environment(pos))

assignInMyNamespace(x, value)

fixInNamespace(x, ns, pos = -1, envir = as.environment(pos), ...)
```

## Arguments

|                    |                                                             |
|--------------------|-------------------------------------------------------------|
| <code>x</code>     | an object name (given as a character string).               |
| <code>value</code> | an R object.                                                |
| <code>ns</code>    | a namespace, or character string giving the namespace.      |
| <code>pos</code>   | where to look for the object: see <a href="#">get</a> .     |
| <code>envir</code> | an alternative way to specify an environment to look in.    |
| <code>...</code>   | arguments to pass to the editor: see <a href="#">edit</a> . |

## Details

`assignInMyNamespace` is intended to be called from functions within a package, and chooses the namespace as the environment of the function calling it.

The namespace can be specified in several ways. Using, for example, `ns = "stats"` is the most direct, but a loaded package can be specified via any of the methods used for [get](#): `ns` can also be the environment printed as `'<namespace:foo>'`.

`getFromNamespace` is similar to (but predates) the `:::` operator: it is more flexible in how the namespace is specified.

`fixInNamespace` invokes [edit](#) on the object named `x` and assigns the revised object in place of the original object. For compatibility with `fix`, `x` can be unquoted.

## Value

`getFromNamespace` returns the object found (or gives an error).

`assignInNamespace`, `assignInMyNamespace` and `fixInNamespace` are invoked for their side effect of changing the object in the namespace.

## Warning

`assignInNamespace` should not be used in final code, and will in future throw an error if called from a package. Already certain uses are disallowed.

## Note

`assignInNamespace`, `assignInMyNamespace` and `fixInNamespace` change the copy in the namespace, but not any copies already exported from the namespace, in particular an object of that name in the package (if already attached) and any copies already imported into other namespaces. They are really intended to be used *only* for objects which are not exported from the namespace. They do attempt to alter a copy registered as an S3 method if one is found.

They can only be used to change the values of objects in the namespace, not to create new objects.

## See Also

[get](#), [fix](#), [getS3method](#)

Examples

```
getFromNamespace("findGeneric", "utils")
## Not run:
fixInNamespace("predict.ppr", "stats")
stats::predict.ppr
getS3method("predict", "ppr")
## alternatively
fixInNamespace("predict.ppr", pos = 3)
fixInNamespace("predict.ppr", pos = "package:stats")

## End(Not run)
```

| getParseData | <i>Get Detailed Parse Information from Object</i> |
|--------------|---------------------------------------------------|

---

Description

If the "keep.source" option is TRUE, R's parser will attach detailed information on the object it has parsed. These functions retrieve that information.

Usage

```
getParseData(x, includeText = NA)
getParseText(parseData, id)
```

Arguments

|             |                                                                                                                     |
|-------------|---------------------------------------------------------------------------------------------------------------------|
| x           | an expression returned from <a href="#">parse</a> , or a function or other object with source reference information |
| includeText | logical; whether to include the text of parsed items in the result                                                  |
| parseData   | a data frame returned from <code>getParseData</code>                                                                |
| id          | a vector of item identifiers whose text is to be retrieved                                                          |

Details

In version 3.0.0, the R parser was modified to include code written by Romain Francois in his **parser** package. This constructs a detailed table of information about every token and higher level construct in parsed code. This table is stored in the [srcfile](#) record associated with source references in the parsed code, and retrieved by the `getParseData` function.

Value

For `getParseData`:  
If parse data is not present, NULL. Otherwise a data frame is returned, containing the following columns:

|       |                                                                                                                                                                   |
|-------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| line1 | integer. The line number where the item starts. This is the parsed line number called "parse" in <a href="#">getSrcLocation</a> , which ignores #line directives. |
| col1  | integer. The column number where the item starts. The first character is column 1. This corresponds to "column" in <a href="#">getSrcLocation</a> .               |
| line2 | integer. The line number where the item ends.                                                                                                                     |

|          |                                                                                                                                                                                                                                                                                                                                      |
|----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| col2     | integer. The column number where the item ends.                                                                                                                                                                                                                                                                                      |
| id       | integer. An identifier associated with this item.                                                                                                                                                                                                                                                                                    |
| parent   | integer. The id of the parent of this item.                                                                                                                                                                                                                                                                                          |
| token    | character string. The type of the token.                                                                                                                                                                                                                                                                                             |
| terminal | logical. Whether the token is “terminal”, i.e. a leaf in the parse tree.                                                                                                                                                                                                                                                             |
| text     | character string. If includeText is TRUE, the text of all tokens; if it is NA (the default), the text of terminal tokens. If includeText == FALSE, this column is not included. Very long strings (with source of 1000 characters or more) will not be stored; a message giving their length and delimiter will be included instead. |

The rownames of the data frame will be equal to the id values, and the data frame will have a "srcfile" attribute containing the [srcfile](#) record which was used. The rows will be ordered by starting position within the source file, with parent items occurring before their children.

For getParseText:

A character vector of the same length as id containing the associated text items. If they are not included in parseData, they will be retrieved from the original file.

### Note

There are a number of differences in the results returned by getParseData relative to those in the original **parser** code:

- Fewer columns are kept.
- The internal token number is not returned.
- col1 starts counting at 1, not 0.
- The id values are not attached to the elements of the parse tree, they are only retained in the table returned by getParseData.
- #line directives are identified, but other comment markup (e.g., **roxygen2** comments) are not.

Parse data by design explore details of the parser implementation, which are subject to change without notice. Applications computing on the parse data may require updates for each R release.

### Examples

```
fn <- function(x) {
  x + 1 # A comment, kept as part of the source
}

d <- getParseData(fn)
```

```
if (!is.null(d)) {  
  plus <- which(d$token == "'+'")  
  sum <- d$parent[plus]  
  print(d[as.character(sum),])  
  print(getParseText(d, sum))  
}
```

---

`getS3method`*Get an S3 Method*

---

## Description

Get a method for an S3 generic, possibly from a namespace or the generic's registry.

## Usage

```
getS3method(f, class, optional = FALSE, envir = parent.frame())
```

## Arguments

|                       |                                                                                         |
|-----------------------|-----------------------------------------------------------------------------------------|
| <code>f</code>        | a character string giving the name of the generic.                                      |
| <code>class</code>    | a character string giving the name of the class.                                        |
| <code>optional</code> | logical: should failure to find the generic or a method be allowed?                     |
| <code>envir</code>    | the <a href="#">environment</a> in which the method and its generic are searched first. |

## Details

S3 methods may be hidden in namespaces, and will not then be found by [get](#): this function can retrieve such functions, primarily for debugging purposes.

Further, S3 methods can be registered on the generic when a namespace is loaded, and the registered method will be used if none is visible (using namespace scoping rules).

It is possible that which S3 method will be used may depend on where the generic `f` is called from: `getS3method` returns the method found if `f` were called from the same environment.

## Value

The function found, or NULL if no function is found and `optional = TRUE`.

## Examples

```
require(stats)  
exists("predict.ppr") # false  
getS3method("predict", "ppr")
```

---

getWindowsHandle      *Get a Windows Handle*

---

### Description

Get the Windows handle of a window or of the R process in MS Windows.

### Usage

```
getWindowsHandle(which = "Console")
```

### Arguments

**which**                      a string (see below), or the number of a graphics device window (which must be a [windows](#) one).

### Details

getWindowsHandle gets the Windows handle. Possible choices for which are:

|                 |                                        |
|-----------------|----------------------------------------|
| "Console"       | The console window handle.             |
| "Frame"         | The MDI frame window handle.           |
| "Process"       | The process pseudo-handle.             |
| A device number | The window handle of a graphics device |

These values are not normally useful to users, but may be used by developers making addons to R. NULL is returned for the Frame handle if not running in MDI mode, for the Console handle when running Rterm, for any unrecognized string for which, or for a graphics device with no corresponding window.

Other windows (help browsers, etc.) are not accessible through this function.

### Value

An external pointer holding the Windows handle, or NULL.

### Note

This is only available on Windows.

### See Also

[getIdentification](#), [getWindowsHandles](#)

### Examples

```
if(.Platform$OS.type == "windows")
  print( getWindowsHandle() )
```

---

|                   |                                                      |
|-------------------|------------------------------------------------------|
| getWindowsHandles | <i>Get handles of Windows in the MS Windows RGui</i> |
|-------------------|------------------------------------------------------|

---

### Description

This function gets the Windows handles of visible top level windows or windows within the R MDI frame (when using the Rgui).

### Usage

```
getWindowsHandles(which = "R", pattern = "", minimized = FALSE)
```

### Arguments

|           |                                                                                        |
|-----------|----------------------------------------------------------------------------------------|
| which     | A vector of strings "R" or "all" (possibly with repetitions). See the Details section. |
| pattern   | A vector of patterns that the titles of the windows must match.                        |
| minimized | A logical vector indicating whether minimized windows should be considered.            |

### Details

This function will search for Windows handles, for passing to external GUIs or to the [arrangeWindows](#) function. Each of the arguments may be a vector of values. These will be treated as follows:

- The arguments will all be recycled to the same length.
- The corresponding elements of each argument will be applied in separate searches.
- The final result will be the union of the windows identified in each of the searches.

If an element of which is "R", only windows belonging to the current R process will be returned. In MDI mode, those will be the child windows within the R GUI (Rgui) frame. In SDI mode, all windows belonging to the process will be included.

If the element is "all", then top level windows will be returned.

The elements of pattern will be used to make a subset of windows whose title text matches (according to [grep](#)) the pattern.

If minimized = FALSE, minimized windows will be ignored.

### Value

A list of external pointers containing the window handles.

### Note

This is only available on Windows.

**Examples**

```
if(.Platform$OS.type == "windows") withAutoprint({
  getWindowsHandles()
  getWindowsHandles("all")
})
```

---

 glob2rx

---

*Change Wildcard or Globbing Pattern into Regular Expression*

---

**Description**

Change *wildcard* aka *globbing* patterns into the corresponding regular expressions ([regex](#)).

This is also a practical didactical example for the use of [sub\(\)](#) and regular expressions.

**Usage**

```
glob2rx(pattern, trim.head = FALSE, trim.tail = TRUE)
```

**Arguments**

|           |                                                                                         |
|-----------|-----------------------------------------------------------------------------------------|
| pattern   | character vector                                                                        |
| trim.head | logical specifying if leading " <code>^.*</code> " should be trimmed from the result.   |
| trim.tail | logical specifying if trailing " <code>.*\$</code> " should be trimmed from the result. |

**Details**

This takes a wildcard as used by most shells and returns an equivalent regular expression. ‘?’ is mapped to ‘.’ (match a single character), ‘\*’ to ‘.’ (match any string, including an empty one), and the pattern is anchored (it must start at the beginning and end at the end). Optionally, the resulting regexp is simplified.

Note that now even ‘(’, ‘[’ and ‘{’ can be used in pattern, but `glob2rx()` may not work correctly with arbitrary characters in pattern, for example escaped special characters.

**Value**

A character vector of the same length as the input pattern where each wildcard is translated to the corresponding regular expression.

**Author(s)**

Martin Maechler, Unix/sed based version, 1991; current: 2004

**See Also**

[regex](#) about regular expression, [sub](#), etc about substitutions using regexps. [Sys.glob](#) does wildcard expansion, i.e., “globbing” on file paths more subtly, e.g., allowing to escape special characters.

Examples

```
stopifnot(glob2rx("abc.*") == "^abc\\.","
  glob2rx("a?b.*") == "^a.b\\.","
  glob2rx("a?b.*", trim.tail = FALSE) == "^a.b\\..*$",
  glob2rx("*.doc") == "^.*\\.doc$",
  glob2rx("*.doc", trim.head = TRUE) == "\\doc$",
  glob2rx("*.t*") == "^.*\\.t",
  glob2rx("*.t??") == "^.*\\.t..$",
  glob2rx("[*]") == "^.*\\"
)
```

---

|                 |                                                |
|-----------------|------------------------------------------------|
| globalVariables | <i>Declarations Used in Checking a Package</i> |
|-----------------|------------------------------------------------|

---

Description

For `globalVariables`, the names supplied are of functions or other objects that should be regarded as defined globally when the check tool is applied to this package. The call to `globalVariables` will be included in the package’s source. Repeated calls in the same package accumulate the names of the global variables.

Typical examples are the fields and methods in reference classes, which appear to be global objects to **codetools**. (This case is handled automatically by `setRefClass()` and friends, using the supplied field and method names.)

For `suppressForeignCheck`, the names supplied are of variables used as `.NAME` in foreign function calls which should not be checked by `checkFF(registration = TRUE)`. Without this declaration, expressions other than simple character strings are assumed to evaluate to registered native symbol objects. The type of call (`.Call`, `.External`, etc.) and argument counts will be checked. With this declaration, checks on those names will usually be suppressed. (If the code uses an expression that should only be evaluated at runtime, the message can be suppressed by wrapping it in a `dontCheck` function call, or by saving it to a local variable, and suppressing messages about that variable. See the example below.)

Usage

```
globalVariables(names, package, add = TRUE)
suppressForeignCheck(names, package, add = TRUE)
```

Arguments

|         |                                                                                                                                                                                                                                                                                                                         |
|---------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| names   | The character vector of object names. If omitted, the current list of global variables declared in the package will be returned, unchanged.                                                                                                                                                                             |
| package | The relevant package, usually the character string name of the package but optionally its corresponding namespace environment.<br><br>When the call to <code>globalVariables</code> or <code>suppressForeignCheck</code> comes in the package’s source file, the argument is normally omitted, as in the example below. |
| add     | Should the contents of names be added to the current global variables or replace it?                                                                                                                                                                                                                                    |

## Details

The lists of declared global variables and native symbol objects are stored in a metadata object in the package's namespace, assuming the `globalVariables` or `suppressForeignCheck` call(s) occur as top-level calls in the package's source code.

The check command, as implemented in package **tools**, queries the list before checking the R source code in the package for possible problems.

`globalVariables` was introduced in R 2.15.1 and `suppressForeignCheck` was introduced in R 3.1.0 so both should be used conditionally: see the example.

## Value

`globalVariables` returns the current list of declared global variables, possibly modified by this call.

`suppressForeignCheck` returns the current list of native symbol objects which are not to be checked.

## Note

The global variables list really belongs to a restricted scope (a function or a group of method definitions, for example) rather than the package as a whole. However, implementing finer control would require changes in `check` and/or in **codetools**, so in this version the information is stored at the package level.

## Author(s)

John Chambers and Duncan Murdoch

## See Also

[dontCheck](#)

## Examples

```
## Not run:
## assume your package has some code that assigns ".obj1" and ".obj2"
## but not in a way that codetools can find.
## In the same source file (to remind you that you did it) add:
if(getRversion() >= "2.15.1") utils::globalVariables(c(".obj1", ".obj2"))

## To suppress messages about a run-time calculated native symbol,
## save it to a local variable.

## At top level, put this:
if(getRversion() >= "3.1.0") utils::suppressForeignCheck("localvariable")

## Within your function, do the call like this:
localvariable <- if (condition) entry1 else entry2
.Call(localvariable, 1, 2, 3)

## HOWEVER, it is much better practice to write code
## that can be checked thoroughly, e.g.
if(condition) .Call(entry1, 1, 2, 3) else .Call(entry2, 1, 2, 3)

## End(Not run)
```

hashtab

*Hash Tables (Experimental)***Description**

Create and manipulate mutable hash tables.

**Usage**

```
hashtab(type = c("identical", "address"), size)
gethash(h, key, nomatch = NULL)
sethash(h, key, value)
remhash(h, key)
numhash(h)
typhash(h)
maphash(h, FUN)
clrhsh(h)
is.hashtab(x)
## S3 method for class 'hashtab'
h[[key, nomatch = NULL, ...]]
## S3 replacement method for class 'hashtab'
h[[key, ...]] <- value
## S3 method for class 'hashtab'
print(x, ...)
## S3 method for class 'hashtab'
format(x, ...)
## S3 method for class 'hashtab'
length(x)
## S3 method for class 'hashtab'
str(object, ...)
```

**Arguments**

|           |                                                                                             |
|-----------|---------------------------------------------------------------------------------------------|
| type      | <a href="#">character</a> string specifying the hash table type.                            |
| size      | an integer specifying the expected number of entries.                                       |
| h, object | a hash table.                                                                               |
| key       | an R object to use as a key.                                                                |
| nomatch   | value to return if key does not match.                                                      |
| value     | new value to associate with key.                                                            |
| FUN       | a <a href="#">function</a> of two arguments, the key and the value, to call for each entry. |
| x         | object to be tested, printed, or formatted.                                                 |
| ...       | additional arguments.                                                                       |

**Details**

Hash tables are a data structure for efficiently associating keys with values. Hash tables are similar to [environments](#), but keys can be arbitrary objects. Like environments, and unlike named lists and most other objects in R, hash tables are mutable, i.e., they are *not* copied when modified and assignment means just giving a new name to the same object.

New hash tables are created by `hashtab`. Two variants are available: keys can be considered to match if they are `identical()` (type = "identical", the default), or if their addresses in memory are equal (type = "address"). The default "identical" type is almost always the right choice. The size argument provides a hint for setting the initial hash table size. The hash table will grow if necessary, but specifying an expected size can be more efficient.

`gethash` returns the value associated with key. If key is not present in the table, then the value of `nomatch` is returned.

`sethash` adds a new key/value association or changes the current value for an existing key. `remhash` removes the entry for key, if there is one.

`maphash` calls FUN for each entry in the hash table with two arguments, the entry key and the entry value. The order in which the entries are processed is not predictable. The consequence of FUN adding entries to the table or deleting entries from the table is also not predictable, except that removing the entry currently being processed will have the desired effect.

`clrhash` removes all entries from the hash table.

## Value

`hashtab` returns a new hash table of the specified type.

`gethash` returns the value associated with key, or `nomatch` if there is no such value.

`sethash` returns value invisibly.

`remhash` invisibly returns TRUE if an entry for key was found and removed, and FALSE if no entry was found.

`numhash` returns the current number of entries in the table.

`typhash` returns a character string specifying the type of the hash table, one of "identical" or "address".

`maphash` and `clrhash` return NULL invisibly.

## Notes

The interface design is based loosely on hash table support in Common Lisp.

The hash function and equality test used for "identical" hash tables are the same as the ones used internally by `duplicated` and `unique`, with two exceptions:

- Closure environments are not ignored when comparing closures. This corresponds to calling `identical()` with `ignore.environment = FALSE`, which is the default for `identical()`.
- External pointer objects are compared as reference objects, corresponding to calling `identical()` with `extptr.as.ref = TRUE`. This ensures that hash tables with keys containing external pointers behave reasonably when serialized and unserialized.

As an experimental feature, the element operator `[[` can also be used to get or set hash table entries, and `length` can be used to obtain the number of entries. It is not yet clear whether this is a good idea.

## Examples

```
## Create a new empty hash table.
h1 <- hashtab()
h1

## Add some key/value pairs.
```

```

sethash(h1, NULL, 1)
sethash(h1, .GlobalEnv, 2)
for (i in seq_along(LETTERS)) sethash(h1, LETTERS[i], i)

## Look up values for some keys.
gethash(h1, NULL)
gethash(h1, .GlobalEnv)
gethash(h1, "Q")

## Remove an entry.
(remhash(h1, NULL))
gethash(h1, NULL)
(remhash(h1, "XYZ"))

## Using the element operator.
h1[["ABC"]]
h1[["ABC", nomatch = 77]]
h1[["ABC"]] <- "DEF"
h1[["ABC"]]

## Integers and real numbers that are equal are considered different
## (not identical) as keys:
identical(3, 3L)
sethash(h1, 3L, "DEF")
gethash(h1, 3L)
gethash(h1, 3)

## Two variables can refer to the same hash table.
h2 <- h1
identical(h1, h2)
## set in one, see in the "other" <==> really one object with 2 names
sethash(h2, NULL, 77)
gethash(h1, NULL)
str(h1)

## An example of using maphash(): get all hashkeys of a hash table:
hashkeys <- function(h) {
  val <- vector("list", numhash(h))
  idx <- 0
  maphash(h, function(k, v) { idx <- idx + 1
                              val[idx] <- list(k) })
  val
}

kList <- hashkeys(h1)
str(kList) # the *order* is "arbitrary" & cannot be "known"

```

---

hasName

*Check for Name*

---

## Description

hasName is a convenient way to test for one or more names in an R object.

**Usage**

```
hasName(x, name)
```

**Arguments**

|      |                                           |
|------|-------------------------------------------|
| x    | Any object.                               |
| name | One or more character values to look for. |

**Details**

hasName(x, name) is defined to be equivalent to name %in% names(x), though it will evaluate slightly more quickly. It is intended to replace the common idiom !is.null(x\$name). The latter can be unreliable due to partial name matching; see the example below.

**Value**

A logical vector of the same length as name containing TRUE if the corresponding entry is in names(x).

**See Also**

[%in%](#), [exists](#)

**Examples**

```
x <- list(abc = 1, def = 2)
!is.null(x$abc) # correct
!is.null(x$a)   # this is the wrong test!
hasName(x, "abc")
hasName(x, "a")
```

---

head

---

*Return the First or Last Parts of an Object*

---

**Description**

Returns the first or last parts of a vector, matrix, array, table, data frame or function. Since head() and tail() are generic functions, they have been extended to other classes, including "ts" from stats.

**Usage**

```
head(x, ...)
## Default S3 method:
head(x, n = 6L, ...)
## S3 method for class 'matrix'
head(x, n = 6L, ...) # is exported as head.matrix()
## NB: The methods for 'data.frame' and 'array' are identical to the 'matrix' one

## S3 method for class 'ftable'
head(x, n = 6L, ...)
## S3 method for class 'function'
```

```

head(x, n = 6L, ...)

tail(x, ...)
## Default S3 method:
tail(x, n = 6L, keepnums = FALSE, addrownums, ...)
## S3 method for class 'matrix'
tail(x, n = 6L, keepnums = TRUE, addrownums, ...) # exported as tail.matrix()
## NB: The methods for 'data.frame', 'array', and 'table'
##      are identical to the 'matrix' one

## S3 method for class 'ftable'
tail(x, n = 6L, keepnums = FALSE, addrownums, ...)
## S3 method for class 'function'
tail(x, n = 6L, ...)

.checkHT(n, d)

```

## Arguments

|                         |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|-------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>          | an object                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <code>n</code>          | an integer vector of length up to <code>dim(x)</code> (or 1, for non-dimensioned objects). A logical is silently coerced to integer. Values specify the indices to be selected in the corresponding dimension (or along the length) of the object. A positive value of <code>n[i]</code> includes the first/last <code>n[i]</code> indices in that dimension, while a negative value excludes the last/first <code>abs(n[i])</code> , including all remaining indices. NA or non-specified values (when <code>length(n) &lt; length(dim(x))</code> ) select all indices in that dimension. Must contain at least one non-missing value. |
| <code>keepnums</code>   | in each dimension, if no names in that dimension are present, create them using the indices included in that dimension. Ignored if <code>dim(x)</code> is NULL or its length 1.                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <code>addrownums</code> | deprecated - <code>keepnums</code> should be used instead. Taken as the value of <code>keepnums</code> if it is explicitly set when <code>keepnums</code> is not.                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <code>...</code>        | arguments to be passed to or from other methods.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <code>d</code>          | typically <code>dim(x)</code> , hence NULL or a (typically integer, short) vector.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

## Details

For vector/array based objects, `head()` (`tail()`) returns a subset of the same dimensionality as `x`, usually of the same class. For historical reasons, by default they select the first (last) 6 indices in the first dimension ("rows") or along the length of a non-dimensioned vector, and the full extent (all indices) in any remaining dimensions. `head.matrix()` and `tail.matrix()` are exported.

The default and array(/matrix) methods for `head()` and `tail()` are quite general. They will work as is for any class which has a `dim()` method, a `length()` method (only required if `dim()` returns NULL), and a `[]` method (that accepts the drop argument and can subset in all dimensions in the dimensioned case).

For functions, the lines of the deparsed function are returned as character strings.

When `x` is an array(/matrix) of dimensionality two and more, `tail()` will add `dimnames` similar to how they would appear in a full printing of `x` for all dimensions `k` where `n[k]` is specified and non-missing and `dimnames(x)[[k]]` (or `dimnames(x)` itself) is NULL. Specifically, the form of the added `dimnames` will vary for different dimensions as follows:

k=1 (**rows**): "[n,]" (right justified with whitespace padding)

k=2 (**columns**): "[,n]" (with *no* whitespace padding)

k>2 (**higher dims**): "n", i.e., the indices as *character* values

Setting keepnums = FALSE suppresses this behaviour.

As `data.frame` subsetting ('indexing') keeps `attributes`, so do the `head()` and `tail()` methods for data frames.

The auxiliary function `.checkHT(d, n)` is useful in `head(x, n)` or `tail(x, n)` methods, checking validity of `d <- dim(x)` and `n`.

## Value

An object (usually) like `x` but generally smaller. Hence, for `arrays`, the result corresponds to `x[. . , drop=FALSE]`. For `ftable` objects `x`, a transformed `format(x)`.

## Note

For array inputs the output of `tail` when `keepnums` is `TRUE`, any `dimnames` vectors added for dimensions >2 are the original numeric indices in that dimension *as character vectors*. This means that, e.g., for 3-dimensional array `arr`, `tail(arr, c(2,2,-1))[, , 2]` and `tail(arr, c(2,2,-1))[, , "2"]` may both be valid but have completely different meanings.

## Author(s)

Patrick Burns, improved and corrected by R-Core. Negative argument added by Vincent Goulet. Multi-dimension support added by Gabriel Becker.

## Examples

```
head(letters)
head(letters, n = -6L)

head(freeny.x, n = 10L)
head(freeny.y)

head(gait) # 3d array
head(gait, c(6L, 2L))
head(gait, c(6L, 2L, -1L))

tail(letters)
tail(letters, n = -6L)

tail(freeny.x)
## the bottom-right "corner" :
tail(freeny.x, n = c(4, 2))
tail(freeny.y)

tail(gait)
tail(gait, c(6L, 2L))
tail(gait, c(6L, 2L, -1L))

## gait without dimnames --> keepnums showing original row/col numbers
a3 <- gait ; dimnames(a3) <- NULL
tail(a3, c(6, 2, -1))# keepnums = TRUE is default here!
tail(a3, c(6, 2, -1), keepnums = FALSE)
```

```
## data frame w/ a (non-standard) attribute:
treeS <- structure(trees, foo = "bar")
(n <- nrow(treeS))
stopifnot(exprs = { # attribute is kept
  identical(htS <- head(treeS), treeS[1:6, ])
  identical(attr(htS, "foo") , "bar")
  identical(tlS <- tail(treeS), treeS[(n-5):n, ])
  ## BUT if I use "useAttrib(.)", this is not ok, when n is of length 2:
  ## --- because [i,j]-indexing of data frames also drops "other" attributes ..
  identical(tail(treeS, 3:2), treeS[(n-2):n, 2:3] )
})

tail(library) # last lines of function

head(stats::ftable(Titanic))

## 1d-array (with named dim) :
a1 <- array(1:7, 7); names(dim(a1)) <- "02"
stopifnot(exprs = {
  identical( tail(a1, 10), a1)
  identical( head(a1, 10), a1)
  identical( head(a1, 1), a1 [1 , drop=FALSE] ) # was a1[1] in R <= 3.6.x
  identical( tail(a1, 2), a1[6:7])
  identical( tail(a1, 1), a1 [7 , drop=FALSE] ) # was a1[7] in R <= 3.6.x
})
```

help

Documentation

---

## Description

help is the primary interface to the help systems.

## Usage

```
help(topic, package = NULL, lib.loc = NULL,
      verbose = getOption("verbose"),
      try.all.packages = getOption("help.try.all.packages"),
      help_type = getOption("help_type"))
```

## Arguments

|         |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|---------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| topic   | usually, a <a href="#">name</a> or character string specifying the topic for which help is sought. A character string (enclosed in explicit single or double quotes) is always taken as naming a topic.<br><br>If the value of topic is a length-one character vector the topic is taken to be the value of the only element. Otherwise topic must be a name or a <a href="#">reserved</a> word (if syntactically valid) or character string.<br><br>See ‘Details’ for what happens if this is omitted. |
| package | a name or character vector giving the packages to look into for documentation, or NULL. By default, all packages whose namespaces are loaded are used. To avoid a name being deparsed use e.g. (pkg_ref) (see the examples).                                                                                                                                                                                                                                                                            |

|                               |                                                                                                                                                                                                                                                                       |
|-------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>lib.loc</code>          | a character vector of directory names of R libraries, or NULL. The default value of NULL corresponds to all libraries currently known. If the default is used, the loaded packages are searched before the libraries. This is not used for HTML help (see ‘Details’). |
| <code>verbose</code>          | logical; if TRUE, the file name is reported.                                                                                                                                                                                                                          |
| <code>try.all.packages</code> | logical; see Note.                                                                                                                                                                                                                                                    |
| <code>help_type</code>        | character string: the type of help required. Possible values are "text", "html" and "pdf". Case is ignored, and partial matching is allowed.                                                                                                                          |

## Details

The following types of help are available:

- Plain text help
- HTML help pages with hyperlinks to other topics, shown in a browser by [browseURL](#). (On Unix-alikes, where possible an existing browser window is re-used: the macOS GUI uses its own browser window.)  
If for some reason HTML help is unavailable (see [startDynamicHelp](#)), plain text help will be used instead.
- For help only, typeset as PDF – see the section on ‘Offline help’.

**On Unix-alikes:** The ‘factory-fresh’ default is text help except from the macOS GUI, which uses HTML help displayed in its own browser window.

**On Windows:** The default for the type of help is selected when R is installed – the ‘factory-fresh’ default is HTML help.

The rendering of text help will use directional quotes in suitable locales (UTF-8 and single-byte Windows locales): sometimes the fonts used do not support these quotes so this can be turned off by setting [options](#)(useFancyQuotes = FALSE).

`topic` is not optional: if it is omitted R will give

- If a package is specified, (text or, in interactive use only, HTML) information on the package, including hints/links to suitable help topics.
- If `lib.loc` only is specified, a (text) list of available packages.
- Help on help itself if none of the first three arguments is specified.

Some topics need to be quoted (by [backticks](#)) or given as a character string. These include those which cannot syntactically appear on their own such as unary and binary operators, function and control-flow [reserved](#) words (including `if`, `else`, `for`, `in`, `repeat`, `while`, `break` and `next`). The other reserved words can be used as if they were names, for example `TRUE`, `NA` and `Inf`.

If multiple help files matching `topic` are found, in interactive use a menu is presented for the user to choose one: in batch use the first on the search path is used. (For HTML help the menu will be an HTML page, otherwise a graphical menu if possible if [getOption](#)("menu.graphics") is true, the default.)

Note that HTML help does not make use of `lib.loc`: it will always look first in the loaded packages and then along `.libPaths()`.

## Offline help

Typeset documentation is produced by running the LaTeX version of the help page through `pdflatex`: this will produce a PDF file.

The appearance of the output can be customized through a file `'Rhelp.cfg'` somewhere in your LaTeX search path: this will be input as a LaTeX style file after `Rd.sty`. Some [environment variables](#) are consulted, notably `R_PAPERSIZE` (via `getOption("papersize")`) and `R_RD4PDF` (see 'Making manuals' in the 'R Installation and Administration' manual).

If there is a function `offline_help_helper` in the workspace or further down the search path it is used to do the typesetting, otherwise the function of that name in the `utils` namespace (to which the first paragraph applies). It should accept at least three arguments, the name of the LaTeX file to be typeset, the type (which is nowadays ignored), and a logical `msg` indicating if a `message()` about the pdf creation should be signalled. It accepts also an argument `texinputs`, which will give the graphics path when the help document contains figures, and will otherwise not be supplied.

## Note

Unless `lib.loc` is specified explicitly, the loaded packages are searched before those in the specified libraries. This ensures that if a library is loaded from a library not in the known library trees, then the help from the loaded library is used. If `lib.loc` is specified explicitly, the loaded packages are *not* searched.

If this search fails and argument `try.all.packages` is `TRUE` and neither packages nor `lib.loc` is specified, then all the packages in the known library trees are searched for help on topic and a list of (any) packages where help may be found is displayed (with hyperlinks for `help_type = "html"`). **NB:** searching all packages can be slow, especially the first time (caching of files by the OS can expedite subsequent searches dramatically).

## See Also

[?](#) for shortcuts to help topics.

[help.search\(\)](#) or [??](#) for finding help pages on a vague topic; [help.start\(\)](#) which opens the HTML version of the R help pages; [library\(\)](#) for listing available packages and the help objects they contain; [data\(\)](#) for listing available data sets; [methods\(\)](#).

Use [prompt\(\)](#) to get a prototype for writing help pages of your own package.

## Examples

```
help()
help(help)           # the same

help(lapply)

help("for")          # or ?"for", but quotes/backticks are needed

try({# requires working TeX installation:
  help(dgamma, help_type = "pdf")
## -> nicely formatted pdf -- including math formula -- for help(dgamma):
  system2(getOption("pdfviewer"), "dgamma.pdf", wait = FALSE)
```

```

}))

help(package = "splines") # get help even when package is not loaded

topi <- "women"
help(topi)

try(help("bs", try.all.packages = FALSE)) # reports not found (an error)
help("bs", try.all.packages = TRUE)      # reports can be found
                                         # in package 'splines'

## For programmatic use:
topic <- "family"; pkg_ref <- "stats"
help((topic), (pkg_ref))

```

help.request

*Send a Post to R-help*

## Description

Prompts the user to check they have done all that is expected of them before sending a post to the R-help mailing list, provides a template for the post with session information included and optionally sends the email (on Unix systems).

## Usage

```

help.request(subject = "",
             address = "r-help@R-project.org",
             file = "R.help.request", ...)

```

## Arguments

|         |                                                                                                                             |
|---------|-----------------------------------------------------------------------------------------------------------------------------|
| subject | subject of the email. Please do not use single quotes (') in the subject! Post separate help requests for multiple queries. |
| address | recipient's email address.                                                                                                  |
| file    | filename to use (if needed) for setting up the email.                                                                       |
| ...     | additional named arguments such as method and ccaddress to pass to <a href="#">create.post</a> .                            |

## Details

This function is not intended to replace the posting guide. Please read the guide before posting to R-help or using this function (see <https://www.r-project.org/posting-guide.html>).

The `help.request` function:

- asks whether the user has consulted relevant resources, stopping and opening the relevant URL if a negative response is given.
- checks whether the current version of R is being used and whether the add-on packages are up-to-date, giving the option of updating where necessary.
- asks whether the user has prepared appropriate (minimal, reproducible, self-contained, commented) example code ready to paste into the post.

Once this checklist has been completed a template post is prepared including current session information, and passed to [create.post](#).

**Value**

Nothing useful.

**Author(s)**

Heather Turner, based on the then current code and help page of `bug.report()`.

**See Also**

The posting guide (<https://www.r-project.org/posting-guide.html>), also `sessionInfo()` from which you may add to the help request.

`create.post`.

---

help.search

---

*Search the Help System*

---

**Description**

Allows for searching the help system for documentation matching a given character string in the (file) name, alias, title, concept or keyword entries (or any combination thereof), using either [fuzzy matching](#) or [regular expression](#) matching. Names and titles of the matched help entries are displayed nicely formatted.

Vignette names, titles and keywords and demo names and titles may also be searched.

**Usage**

```
help.search(pattern, fields = c("alias", "concept", "title"),
            apropos, keyword, whatis, ignore.case = TRUE,
            package = NULL, lib.loc = NULL,
            help.db = getOption("help.db"),
            verbose = getOption("verbose"),
            rebuild = FALSE, agrep = NULL, use_UTF8 = FALSE,
            types = getOption("help.search.types"))
??pattern
field??pattern
```

**Arguments**

|         |                                                                                                                                                                                                                                                                                                                                                                                                  |
|---------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| pattern | a character string to be matched in the specified fields. If this is given, the arguments apropos, keyword, and whatis are ignored.                                                                                                                                                                                                                                                              |
| fields  | a character vector specifying the fields of the help database to be searched. The entries must be abbreviations of "name", "title", "alias", "concept", and "keyword", corresponding to the help page's (file) name, its title, the topics and concepts it provides documentation for, and the keywords it can be classified to. See below for details and how vignettes and demos are searched. |
| apropos | a character string to be matched in the help page topics and title.                                                                                                                                                                                                                                                                                                                              |
| keyword | a character string to be matched in the help page 'keywords'. 'Keywords' are really categories: the standard categories are listed in file 'R.home("doc")/KEYWORDS' (see also the example) and some package writers have defined their own. If keyword is specified, agrep defaults to FALSE.                                                                                                    |

|                          |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|--------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>what is</code>     | a character string to be matched in the help page topics.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <code>ignore.case</code> | a logical. If TRUE, case is ignored during matching; if FALSE, pattern matching is case sensitive.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <code>package</code>     | a character vector with the names of packages to search through, or NULL in which case <i>all</i> available packages in the library trees specified by <code>lib.loc</code> are searched.                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <code>lib.loc</code>     | a character vector describing the location of R library trees to search through, or NULL. The default value of NULL corresponds to all libraries currently known.                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <code>help.db</code>     | a character string giving the file path to a previously built and saved help database, or NULL.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <code>verbose</code>     | logical; if TRUE, the search process is traced. Integer values are also accepted, with TRUE being equivalent to 2, and 1 being less verbose. On Windows a progress bar is shown during rebuilding, and on Unix a heartbeat is shown for <code>verbose = 1</code> and a package-by-package list for <code>verbose &gt;= 2</code> .                                                                                                                                                                                                                                                                                            |
| <code>rebuild</code>     | a logical indicating whether the help database should be rebuilt. This will be done automatically if <code>lib.loc</code> or the search path is changed, or if package is used and a value is not found.                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <code>agrep</code>       | if NULL (the default unless keyword is used) and the character string to be matched consists of alphanumeric characters, whitespace or a dash only, approximate (fuzzy) matching via <a href="#">agrep</a> is used unless the string has fewer than 5 characters; otherwise, it is taken to contain a <a href="#">regular expression</a> to be matched via <a href="#">grep</a> . If FALSE, approximate matching is not used. Otherwise, one can give a numeric or a list specifying the maximal distance for the approximate match, see argument <code>max.distance</code> in the documentation for <a href="#">agrep</a> . |
| <code>use_UTF8</code>    | logical: should results be given in UTF-8 encoding? Also changes the meaning of regexps in <code>agrep</code> to be Perl regexps.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <code>types</code>       | a character vector listing the types of documentation to search. The entries must be abbreviations of "vignette" "help" or "demo". Results will be presented in the order specified.                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <code>field</code>       | a single value of fields to search.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

## Details

Upon installation of a package, a pre-built help.search index is serialized as 'hsearch.rds' in the 'Meta' directory (provided the package has any help pages). Vignettes are also indexed in the 'Meta/vignette.rds' file. These files are used to create the help search database via [hsearch\\_db](#).

The arguments `apropos` and `what is` play a role similar to the Unix commands with the same names.

Searching with `agrep = FALSE` will be several times faster than the default (once the database is built). However, approximate searches should be fast enough (around a second with 5000 packages installed).

If possible, the help database is saved in memory for use by subsequent calls in the session.

Note that currently the aliases in the matching help files are not displayed.

As with [?](#), in `??` the pattern may be prefixed with a package name followed by `::` or `:::` to limit the search to that package.

For help files, '\keyword' entries which are not among the standard keywords as listed in file 'KEYWORDS' in the R documentation directory are taken as concepts. For standard keyword entries different from 'internal', the corresponding descriptions from file 'KEYWORDS' are additionally taken as concepts. All '\concept' entries are used as concepts.

Vignettes are searched as follows. The "name" and "alias" are both the base of the vignette filename, and the "concept" entries are taken from the '\VignetteKeyword' entries. Vignettes are not classified using the help system "keyword" classifications. Demos are handled similarly to vignettes, without the "concept" search.

## Value

The results are returned in a list object of class "hsearch", which has a print method for nicely formatting the results of the query. This mechanism is experimental, and may change in future versions of R.

In R.app on macOS, this will show up a browser with selectable items. On exiting this browser, the help pages for the selected items will be shown in separate help windows.

The internal format of the class is undocumented and subject to change.

## See Also

[hsearch\\_db](#) for more information on the help search database employed, and for utilities to inspect available concepts and keywords.

[help](#); [help.start](#) for starting the hypertext (currently HTML) version of R's online documentation, which offers a similar search mechanism.

[RSiteSearch](#) to access an on-line search of R resources.

[apropos](#) uses regexps and has nice examples.

## Examples

```
## Not run:
help.search("linear models") # In case you forgot how to fit linear models

## End(Not run)
help.search("non-existent topic")

??utils::help # All the topics matching "help" in the utils package

## Documentation with topic/concept/title matching 'print'
## (disabling fuzzy matching to not also match 'point')
help.search("print", agrep = FALSE)
help.search(apropos = "print", agrep = FALSE) # ignores concepts

## Help pages with documented topics starting with 'try':
help.search("^try", fields = "alias")
alias??"^try" # the same

## Help pages documenting high-level plots:
help.search(keyword = "hplot")

RShowDoc("KEYWORDS") # show all keywords
```

---

help.start*Hypertext Documentation*

---

## Description

Start the hypertext (currently HTML) version of R's online documentation.

## Usage

```
help.start(update = FALSE, gui = "irrelevant",
           lib.loc = .libPaths(),
           browser = getOption("browser"), remote = NULL,
           verbose = getOption("verbose"))
```

## Arguments

|         |                                                                                                                                                                                                                                                                                                       |
|---------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| update  | logical: should this attempt to update the package index to reflect the currently available packages. (Not attempted if remote is non-NULL.)                                                                                                                                                          |
| gui     | just for compatibility with S-PLUS.                                                                                                                                                                                                                                                                   |
| lib.loc | character vector, listing the package libraries to be included.                                                                                                                                                                                                                                       |
| browser | the name of the program to be used as hypertext browser. It should be in the PATH, or a full path specified. Alternatively, it can be an R function which will be called with a URL as its only argument. This option is normally unset on Windows, when the file-association mechanism will be used. |
| remote  | a character string giving a valid URL for the ' <a href="#">R_HOME</a> ' directory on a "remote" location; may be "file://<Rhome>" pointing to a path on your local platform.                                                                                                                         |
| verbose | logical indicating if information about the system interface should be printed to the console.                                                                                                                                                                                                        |

## Details

Unless remote is specified this requires the HTTP server to be available (it will be started if possible: see [startDynamicHelp](#)).

One of the links on the index page is the HTML package index, '[R\\_DOC\\_DIR/html/packages.html](#)', which can be remade by [make.packages.html\(\)](#). For local operation, the HTTP server will remake a temporary version of this list when the link is first clicked, and each time thereafter check if updating is needed (if [.libPaths](#) has changed or any of the directories has been changed). This can be slow, and using update = TRUE will ensure that the packages list is updated before launching the index page.

Argument remote can be used to point to HTML help published by another R installation: it will typically only show packages from the main library of that installation.

## See Also

[help\(\)](#) for on- and off-line help in other formats.

[make.packages.html](#) for how the '\*.html' pages are created. [browseURL](#) for how the help file is displayed.

[RSiteSearch](#) to access an on-line search of R resources.

## Examples

```
help.start()

## the 'remote' arg can be tested by
help.start(remote = paste0("file://", R.home()))
```

|---------------|------------------------------|
| hsearch-utils | <i>Help Search Utilities</i> |
|---------------|------------------------------|

---

## Description

Utilities for searching the help system.

## Usage

```
hsearch_db(package = NULL, lib.loc = NULL,
            types = getOption("help.search.types"),
            verbose = getOption("verbose"),
            rebuild = FALSE, use_UTF8 = FALSE)
hsearch_db_concepts(db = hsearch_db())
hsearch_db_keywords(db = hsearch_db())
```

## Arguments

|          |                                                                                                                                                                              |
|----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| package  | a character vector with the names of packages to search through, or NULL in which case <i>all</i> available packages in the library trees specified by lib.loc are searched. |
| lib.loc  | a character vector describing the location of R library trees to search through, or NULL. The default value of NULL corresponds to all libraries currently known.            |
| types    | a character vector listing the types of documentation to search. See <a href="#">help.search</a> for details.                                                                |
| verbose  | a logical controlling the verbosity of building the help search database. See <a href="#">help.search</a> for details.                                                       |
| rebuild  | a logical indicating whether the help search database should be rebuilt. See <a href="#">help.search</a> for details.                                                        |
| use_UTF8 | logical: should results be given in UTF-8 encoding?                                                                                                                          |
| db       | a help search database as obtained by calls to hsearch_db().                                                                                                                 |

## Details

hsearch\_db() builds and caches the help search database for subsequent use by [help.search](#). (In fact, re-builds only when forced (rebuild = TRUE) or “necessary”.)

The format of the help search database is still experimental, and may change in future versions. Currently, it consists of four tables: one with base information about all documentation objects found, including their names and titles and unique ids; three more tables contain the individual aliases, concepts and keywords together with the ids of the documentation objects they belong to. Separating out the latter three tables accounts for the fact that a single documentation object may provide several of these entries, and allows for efficient searching.

See the details in [help.search](#) for how searchable entries are interpreted according to help type.

`hsearch_db_concepts()` and `hsearch_db_keywords()` extract all concepts or keywords, respectively, from a help search database, and return these in a data frame together with their total frequencies and the numbers of packages they are used in, with entries sorted in decreasing total frequency.

### Examples

```
db <- hsearch_db()
## Total numbers of documentation objects, aliases, keywords and
## concepts (using the current format):
sapply(db, NROW)
## Can also be obtained from print method:
db
## 10 most frequent concepts:
head(hsearch_db_concepts(), 10)
## 10 most frequent keywords:
head(hsearch_db_keywords(), 10)
```

## INSTALL

### *Install Add-on Packages*

---

### Description

Utility for installing add-on packages.

### Usage

```
R CMD INSTALL [options] [-l lib] pkgs
```

### Arguments

|                      |                                                                                                                                                                                                      |
|----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>pkgs</code>    | a space-separated list with the path names of the packages to be installed. See ‘Details’.                                                                                                           |
| <code>lib</code>     | the path name of the R library tree to install to. Also accepted in the form ‘--library=lib’. Paths including spaces should be quoted, using the conventions for the shell in use.                   |
| <code>options</code> | a space-separated list of options through which in particular the process for building the help files can be controlled. Use <code>R CMD INSTALL --help</code> for the full current list of options. |

### Details

This will stop at the first error, so if you want all the `pkgs` to be tried, call this via a shell loop.

If used as `R CMD INSTALL pkgs` without explicitly specifying `lib`, packages are installed into the library tree rooted at the first directory in the library path which would be used by R run in the current environment.

To install into the library tree *lib*, use `R CMD INSTALL -l lib pkgs`. This prepends `lib` to the library path for duration of the install, so required packages in the installation directory will be found (and used in preference to those in other libraries).

Both `lib` and the elements of `pkgs` may be absolute or relative path names of directories. `pkgs` may also contain names of package archive files: these are then extracted to a temporary directory. These

are tarballs containing a single directory, optionally compressed by gzip, bzip2, xz or compress. Finally, binary package archive files (as created by R CMD INSTALL --build) can be supplied.

Tarballs are by default unpacked by the internal `untar` function: if needed an external tar command can be specified by the environment variable `R_INSTALL_TAR`: please ensure that it can handle the type of compression used on the tarball. (This is sometimes needed for tarballs containing invalid or unsupported sections, and can be faster on very large tarballs. Setting `R_INSTALL_TAR` to `'tar.exe'` has been needed to overcome permissions issues on some Windows systems.)

The package sources can be cleaned up prior to installation by `'--preclean'` or after by `'--clean'`: cleaning is essential if the sources are to be used with more than one architecture or platform.

Some package sources contain a `'configure'` script that can be passed arguments or variables via the option `'--configure-args'` and `'--configure-vars'`, respectively, if necessary. The latter is useful in particular if libraries or header files needed for the package are in non-system directories. In this case, one can use the configure variables `LIBS` and `CPPFLAGS` to specify these locations (and set these via `'--configure-vars'`), see section 'Configuration variables' in 'R Installation and Administration' for more information. (If these are used more than once on the command line they are concatenated.) The configure mechanism can be bypassed using the option `'--no-configure'`.

If the attempt to install the package fails, leftovers are removed. If the package was already installed, the old version is restored. This happens either if a command encounters an error or if the install is interrupted from the keyboard: after cleaning up the script terminates.

For details of the locking which is done, see the section 'Locking' in the help for [install.packages](#).

Option `'--build'` can be used to tar up the installed package for distribution as a binary package (as used on macOS). This is done by `utils::tar` unless environment variable `R_INSTALL_TAR` is set.

By default a package is installed with static HTML help pages if and only if R was: use options `'--html'` and `'--no-html'` to override this.

Packages are not by default installed keeping the source formatting (see the `keep.source` argument to [source](#)): this can be enabled by the option `'--with-keep.source'` or by setting environment variable `R_KEEP_PKG_SOURCE` to yes.

Specifying the `'--install-tests'` option copies the contents of the `'tests'` directory into the package installation. If the `R_ALWAYS_INSTALL_TESTS` environment variable is set to a true value, the tests will be installed even if `'--install-tests'` is omitted.

Use R CMD INSTALL --help for concise usage information, including all the available options.

## Sub-architectures

An R installation can support more than one sub-architecture: currently this is most commonly used for 32- and 64-bit builds on Windows.

For such installations, the default behaviour is to try to install source packages for all installed sub-architectures unless the package has a configure script or a `'src/Makefile'` (or `'src/Makefile.win'` on Windows), when only compiled code for the sub-architecture running R CMD INSTALL is installed.

To install a source package with compiled code only for the sub-architecture used by R CMD INSTALL, use `'--no-multiarch'`. To install just the compiled code for another sub-architecture, use `'--libs-only'`.

There are two ways to install for all available sub-architectures. If the configure script is known to work for both Windows architectures, use flag `'--force-biarch'` (and packages can specify this via a `'Biarch: yes'` field in their DESCRIPTION files). Second, a single tarball can be installed with

```
R CMD INSTALL --merge-multiarch mypkg_version.tar.gz
```

### Staged installation

The default way to install source packages changed in R 3.6.0, so packages are first installed to a temporary location and then (if successful) moved to the destination library directory. Some older packages were written in ways that assume direct installation to the destination library.

Staged installation can currently be overridden by having a line ‘StagedInstall: no’ in the package’s ‘DESCRIPTION’ file, *via* flag ‘--no-staged-install’ or by setting environment variable R\_INSTALL\_STAGED to a false value (e.g. ‘false’ or ‘no’).

Staged installation requires either ‘--pkglock’ or ‘--lock’, one of which is used by default.

### Note

The options do not have to precede ‘pkgs’ on the command line, although it will be more legible if they do. All the options are processed before any packages, and where options have conflicting effects the last one will win.

Some parts of the operation of INSTALL depend on the R temporary directory (see [tempdir](#), usually under ‘/tmp’) having both write and execution access to the account running R. This is usually the case, but if ‘/tmp’ has been mounted as noexec, environment variable TMPDIR may need to be set to a directory from which execution is allowed.

For most recent builds of R the internal untar will handle tarballs compressed by zstd: most (but not all) external tar commands will handle ztd compression and others such as lz4.

---

install.packages

---

*Install Packages from Repositories or Local Files*

---

### Description

Download and install packages from CRAN-like repositories or from local files.

### Usage

```
install.packages(pkgs, lib, repos = getOption("repos"),
  contriburl = contrib.url(repos, type),
  method, available = NULL, destdir = NULL,
  dependencies = NA, type = getOption("pkgType"),
  configure.args = getOption("configure.args"),
  configure.vars = getOption("configure.vars"),
  clean = FALSE, Ncpus = getOption("Ncpus", 1L),
  verbose = getOption("verbose"),
  libs_only = FALSE, INSTALL_opts, quiet = FALSE,
  keep_outputs = FALSE, ...)
```

**Arguments**

|              |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|--------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| pkgs         | <p>character vector of the names of packages whose current versions should be downloaded from the repositories.</p> <p>If repos = NULL, a character vector of file paths,</p> <p><b>on Windows</b>, file paths of '.zip' files containing binary builds of packages. ('http://' and 'file://' URLs are also accepted and the files will be downloaded and installed from local copies.) Source directories or file paths or URLs of archives may be specified with type = "source", but some packages need suitable tools installed (see the 'Details' section).</p> <p><b>On Unix-alikes</b>, these file paths can be source directories or archives or binary package archive files (as created by R CMD build --binary). ('http://' and 'file://' URLs are also accepted and the files will be downloaded and installed from local copies.) On a CRAN build of R for macOS these can be '.tgz' files containing binary package archives. Tilde-expansion will be done on file paths.</p> <p>If this is missing, a listbox of available packages is presented where possible in an interactive R session.</p> |
| lib          | character vector giving the library directories where to install the packages. Recycled as needed. If missing, defaults to the first element of <code>.libPaths()</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| repos        | <p>character vector, the base URL(s) of the repositories to use, e.g., the URL of a CRAN mirror such as "https://cloud.r-project.org". For more details on supported URL schemes see <a href="#">url</a>.</p> <p>Can be NULL to install from local files, directories or URLs: this will be inferred by extension from pkgs if of length one.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| contriburl   | URL(s) of the contrib sections of the repositories. Use this argument if your repository mirror is incomplete, e.g., because you mirrored only the 'contrib' section, or only have binary packages. Overrides argument repos. Incompatible with type = "both".                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| method       | download method, see <a href="#">download.file</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| available    | a matrix as returned by <a href="#">available.packages</a> listing packages available at the repositories, or NULL when the function makes an internal call to <code>available.packages</code> . Incompatible with type = "both".                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| destdir      | directory where downloaded packages are stored. If it is NULL (the default) a subdirectory <code>downloaded_packages</code> of the session temporary directory will be used (and the files will be deleted at the end of the session).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| dependencies | <p>logical indicating whether to also install uninstalled packages which these packages depend on/link to/import/suggest (and so on recursively). Not used if repos = NULL. Can also be a character vector, a subset of <code>c("Depends", "Imports", "LinkingTo", "Suggests", "Enhances")</code>.</p> <p>Only supported if lib is of length one (or missing), so it is unambiguous where to install the dependent packages. If this is not the case it is ignored, with a warning.</p> <p>The default, NA, means <code>c("Depends", "Imports", "LinkingTo")</code>.</p> <p>TRUE means to use <code>c("Depends", "Imports", "LinkingTo", "Suggests")</code> for pkgs and <code>c("Depends", "Imports", "LinkingTo")</code> for added dependencies: this installs all the packages needed to run pkgs, their examples, tests and vignettes (if the package author specified them correctly).</p> <p>In all of these, "LinkingTo" is omitted for binary packages.</p>                                                                                                                                             |

|                             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

| <code>type</code>           | character, indicating the type of package to download and install. Will be "source" except on Windows and some macOS builds: see the section on 'Binary packages' for those.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <code>configure.args</code> | (Used only for source installs.) A character vector or a named list. If a character vector with no names is supplied, the elements are concatenated into a single string (separated by a space) and used as the value for the '--configure-args' flag in the call to R CMD INSTALL. If the character vector has names these are assumed to identify values for '--configure-args' for individual packages. This allows one to specify settings for an entire collection of packages which will be used if any of those packages are to be installed. (These settings can therefore be re-used and act as default settings.)<br><br>A named list can be used also to the same effect, and that allows multi-element character strings for each package which are concatenated to a single string to be used as the value for '--configure-args'. |
| <code>configure.vars</code> | (Used only for source installs.) Analogous to <code>configure.args</code> for flag '--configure-vars', which is used to set environment variables for the configure run.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <code>clean</code>          | a logical value indicating whether to add the '--clean' flag to the call to R CMD INSTALL. This is sometimes used to perform additional operations at the end of the package installation in addition to removing intermediate files.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <code>Ncpus</code>          | the number of parallel processes to use for a parallel install of more than one source package. Values greater than one are supported if the make command specified by <code>Sys.getenv("MAKE", "make")</code> accepts argument '-k -j <Ncpus>'.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <code>verbose</code>        | a logical indicating if some "progress report" should be given.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <code>libs_only</code>      | a logical value: should the '--libs-only' option be used to install only additional sub-architectures for source installs? (See also <code>INSTALL_opts</code> .) This can also be used on Windows to install just the DLL(s) from a binary package, e.g. to add 64-bit DLLs to a 32-bit install.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <code>INSTALL_opts</code>   | an optional character vector of additional option(s) to be passed to R CMD INSTALL for a source package install. E.g., <code>c("--html", "--no-multiarch", "--no-test-load")</code> or, for macOS, <code>"--dsym"</code> .<br><br>Can also be a named list of character vectors to be used as additional options, with names the respective package names.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <code>quiet</code>          | logical: if true, reduce the amount of output. This is <i>not</i> passed to <code>available.packages()</code> in case that is called, on purpose.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <code>keep_outputs</code>   | a logical: if true, keep the outputs from installing source packages in the current working directory, with the names of the output files the package names with '.out' appended (overwriting existing files, possibly from previous installation attempts). Alternatively, a character string giving the directory in which to save the outputs. Ignored when installing from local files.                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <code>...</code>            | further arguments to be passed to <code>download.file</code> , <code>available.packages</code> , or to the functions for binary installs on macOS and Windows (which accept an argument "lock": see the section on 'Locking').                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

## Details

This is the main function to install packages. It takes a vector of names and a destination library, downloads the packages from the repositories and installs them. (If the library is omitted it defaults

to the first directory in `.libPaths()`, with a message if there is more than one.) If `lib` is omitted or is of length one and is not a (group) writable directory, in interactive use the code offers to create a personal library tree (the first element of `Sys.getenv("R_LIBS_USER")`) and install there.

Detection of a writable directory is problematic on Windows: see the ‘Note’ section.

For installs from a repository an attempt is made to install the packages in an order that respects their dependencies. This does assume that all the entries in `lib` are on the default library path for installs (set by environment variable `R_LIBS`).

You are advised to run `update.packages` before `install.packages` to ensure that any already installed dependencies have their latest versions.

## Value

Invisible NULL.

## Binary packages

This section applies only to platforms where binary packages are available: Windows and CRAN builds for macOS.

R packages are primarily distributed as *source* packages, but *binary* packages (a packaging up of the installed package) are also supported, and the type most commonly used on Windows and by the CRAN builds for macOS. This function can install either type, either by downloading a file from a repository or from a local file.

Possible values of `type` for binary packages are either simply `"binary"` to denote the binaries matching the current R, or a string consisting of two or three parts separated by periods: the operating system (`"win"` or `"mac"`), the string `"binary"` and optional build name (e.g., `"big-sur-arm64"`). The last part is optional and currently only used on macOS to disambiguate builds targeting different macOS versions or architectures. Example values: `"win.binary"` for Windows binaries and `"mac.binary.big-sur-arm64"` for macOS 11 (Big Sur) arm64 binaries. The corresponding binary type for the running R can be obtained via `.Platform$pkgType`, however, it may be `"source"` if the build does not support package binaries.

For a binary install from a repository, the function checks for the availability of a source package on the same repository, and reports if the source package has a later version, or is available but no binary version is. This check can be suppressed by using

```
